A FINITE ELEMENT METHOD FOR ALLEN–CAHN EQUATION ON
DEFORMING SURFACE
MAXIM OLSHANSKII*, XIANMIN XU†, AND VLADIMIR YUSHUTIN‡

Abstract. The paper studies an Allen–Cahn-type equation defined on a time-dependent surface as a model of phase separation with order–disorder transition in a thin material layer. By a formal inner-outer expansion, it is shown that the limiting behaviour of the solution is a geodesic mean curvature type flow in reference coordinates. A geometrically unfitted finite element method, known as a trace FEM, is considered for the numerical solution of the equation. The paper provides full stability analysis and convergence analysis that accounts for interpolation errors and an approximate recovery of the geometry.

Key words. Allen–Cahn, surface PDEs, evolving surfaces, Trace FEM, geodesic mean curvature flow

1. Introduction. Phase separation may happen in thin material layers such as polymer films, lipid bilayers, binary alloy interfaces or biophotonic nanostructures. One example of such essentially 2D phenomenon is the lipid rafts formation in a multi-component plasma membrane, while the membrane is advected by an extracellular fluid flow and exhibit tangential motion due to the membrane lateral fluidity [41, 43]. In this and some other applications the thin layer is compliant so that a continuum based model represents it by a surface underdoing radial and lateral deformations. Motivated by these examples we adopt the model of Allen and Cahn [1] to describe the phases evolution on a surface with a prescribed material motion. The model uses a smooth indicator function $u$ (order parameter) to characterize ordered / disordered states and a transition region. This renders the model as diffusive interface approach.

Before applying a numerical method to the derived Allen–Cahn type equation, the paper addresses well-posedness of the problem and the limiting behaviour of $u$ when the width of the transition region tends to zero. The later is done here by extending a standard techniques of inner (with respect to the transition layer) and outer expansions for the solution. In a steady domain the asymptotic behaviour is well known to be the mean curvature flow [11] for the limit sharp interface (or the mean geodesic curvature flow for surfaces [9]). In the case of the deforming surface $\Gamma(t)$ we obtain that the for each time $t$ the material velocity of the sharp interface is defined by (instantaneous) geodesic mean curvature, which can be also seen as a mean curvature type flow in reference coordinates.

The main focus of the paper is a finite element analysis of the Allen–Cahn type equation posed on an evolving surface. The paper introduces a geometrically unfitted finite element method, known as a trace FEM [32, 31], to discretize the problem. The method considers a sharp representation of $\Gamma(t)$ (e.g., as a zero level of a level set function) and uses degrees of freedom tailored to an ambient tetrahedral mesh, which can be chosen independent of the surface and its evolution. The numerical approach benefits from the embedding $\Gamma(t) \subset \mathbb{R}^3$ by using tangential calculus to define surface differential operators. Tangential calculus assumes an extension of functions from $\Gamma(t)$ to its (narrow) neighborhood. The later is also used here to define a time-stepping numerical procedure following the ideas from [24, 34]. We prove stability and error estimates for the numerical method. The error analysis accounts for all type of discretization errors, e.g., those resulting from the time stepping, polynomial interpolation and the geometric consistency error due to a possible inexact integration over $\Gamma(t)$. Besides the difficulties associated with time-dependent domains and the treatment of tangential quantities, the current analysis is complicated by the following factor. While in a stationary domain (e.g., in a non-compliant material surface) the Allen–Cahn model defines the evolution of the order parameter as the $L^2$-gradient flow of the Ginzburg–Landau energy functional, such minimization property fails to hold for time-dependent domains.

Computational methods and numerical analysis for Allen–Cahn type equations in planar and volumetric domains have received much attention in the literature, see e.g. [40, 16, 26, 19, 20]

Thanks to (2.3), the surface Allen–Cahn equation (2.2) can be written in the equivalent form

\[
\frac{\partial u}{\partial t} + \rho \text{div}_\Gamma w = -\rho \kappa (\varepsilon^{-2} f(u) - \text{div}_\Gamma (\rho \nabla \Gamma u)) \quad \text{on } \Gamma(t), \ t \in (0,T).
\]

Likewise, the conservation of mass and the surface Reynolds transport theorem yield the identity

\[
\rho \dot{\rho} + \rho \text{div}_\Gamma w = 0 \quad \text{on } \Gamma(t).
\]

Thanks to (2.3), the surface Allen–Cahn equation (2.2) can be written in the equivalent form

\[
\dot{u} = -\varepsilon^2 f(u) - \frac{1}{\rho} \text{div}_\Gamma (\rho \nabla \Gamma u) \quad \text{on } \Gamma(t), \ t \in (0,T).
\]

The outline of the paper is as follows. In Section 2, we introduce the model. The weak formulation of the problem and its well-posedness are discussed in Section 4. An asymptotic behaviour of the solution to the problem is studied in Section 3. After necessary preliminaries, the numerical method is introduced in Section 5. Error and stability analyses are carried out in Section 6. Section 7 supplements the paper with numerical examples.

2. Allen–Cahn equation on an evolving surface. Consider a material surface \( \Gamma(t) \subset \mathbb{R}^3 \), \( t \in [0,T] \), with density distribution \( \rho : \Gamma(t) \to \mathbb{R} \). Assume \( \Gamma(t) \) is passively advected by a smooth velocity field \( w = w(x,t) \), \( x \in \mathbb{R}^3 \), and for all times \( \Gamma(t) \) stays smooth, closed (\( \partial \Gamma(t) = \emptyset \)), connected and orientable. We are interested in a phase separation process on \( \Gamma(t) \) with a transition between order and disorder states. The state of matter at \( x \in \Gamma(t) \) is characterized by a smooth indicator function \( u(x,t) \), \( u : \Gamma(t) \to [-1,1] \), with \( u \simeq -1 \) in the less ordered phase and \( u \simeq 1 \) in the more ordered phase.

To describe an evolution of phases, we follow the classical approach of Allen and Cahn [1] and assume that an instantaneous change in the order per area \( s(t) \subset \Gamma(t) \) is proportional to the variation of the total specific free energy for \( s(t) \):

\[
\frac{d}{dt} \int_{s(t)} \rho u \, ds = - \int_{s(t)} c_k \frac{\delta \epsilon(u)}{\delta u} \, ds,
\]

where \( c_k \) is a positive kinetic coefficient, and the energy density is given by

\[
\epsilon(u) = \rho \left( \frac{1}{\varepsilon^2} F(u) + |\nabla \Gamma u|^2 \right),
\]

where \( \nabla \Gamma u \) is the tangential gradient of \( u \). The energy of a homogeneous state \( F(u) \) has a double–well form of Ginzburg–Landau potential to allow for phase separation, and \( \epsilon \) is a characteristic width of a transition region between phases. Further we choose \( F(u) = (1-u^2)/2 \).

Application of the surface Reynolds transport theorem (also known as the Leibniz formula for evolving surfaces, e.g., [10]) to (2.1) gives

\[
\int_{s(t)} (\dot{\rho}u + \rho u \text{div}_\Gamma w) \, ds = - \int_{s(t)} c_k \frac{\delta \epsilon(u)}{\delta u} \, ds.
\]

By \( \dot{f} \) we denote the material derivative of a smooth function \( f \) defined on \( \Gamma(t) \) for \( t \in [0,T] \) and \( \text{div}_\Gamma \) stands for the surface divergence. Computing the functional derivative of \( F(u) \) with respect to \( u \), \( f(u) = F'(u) \), and varying \( s(t) \) for any fixed \( \Gamma(t) \), \( t \in [0,T] \) leads to the Allen–Cahn equation on the deforming surface:

\[
(\dot{\rho}u + \rho u \text{div}_\Gamma w = -\rho \kappa (\varepsilon^{-2} f(u) - \text{div}_\Gamma (\rho \nabla \Gamma u)) \quad \text{on } \Gamma(t), \ t \in (0,T).
\]

Likewise, the conservation of mass and the surface Reynolds transport theorem yield the identity

\[
\dot{\rho} + \rho \text{div}_\Gamma w = 0 \quad \text{on } \Gamma(t).
\]

Thanks to (2.3), the surface Allen–Cahn equation (2.2) can be written in the equivalent form

\[
\dot{u} = -\kappa \varepsilon^2 f(u) - \frac{1}{\rho} \text{div}_\Gamma (\rho \nabla \Gamma u) \quad \text{on } \Gamma(t), \ t \in (0,T).
\]
The equation should be complemented with the initial condition \( u(x, 0) = u_0(x), \, x \in \Gamma(0) \), describing the state of matter at time \( t = 0 \).

Equations (2.2) or (2.4) are solved for the order parameter \( u \) with given \( \rho \) satisfying (2.3). In this paper, we assume \( \rho = \text{const} \). In practice, this assumption is plausible for surfaces with initially homogeneous density distribution and exhibiting small or area-preserving deformations. The later is characterised by \( \text{div}_\Gamma \mathbf{w} = 0 \) and is a valid assumption for several types of biological membranes, such as lipid mono- or bi-layers [25, 39]. Due to this assumption, the model (slightly) simplifies to the following system of equation and initial condition:

\[
\begin{cases}
\dot{u} = -\epsilon^{-2} f(u) + \Delta_\Gamma u & \text{on } \Gamma(t), \, t \in (0, T), \\
u = u_0 & \text{on } \Gamma(0),
\end{cases}
\]  

(2.5)

\( \Delta_\Gamma \) is the Laplace–Beltrami operator and we set \( c_k = 1 \).

We close this section by noting the analogy between Allen–Cahn equations (2.2) or (2.4) and those describing the compressible two-phase fluid flow (in the Euclidian space) with phase transition; see [2].

### 2.1. Preliminaries

We need more precise assumptions for the evolution of \( \Gamma(t) \). To formulate them, assume that \( \mathbf{w} \) and \( \Gamma_0 \) are sufficiently smooth such that for all \( y \in \Gamma_0 \) the ODE system

\[
\Phi(y, 0) = y, \quad \frac{\partial \Phi}{\partial t}(y, t) = \mathbf{w}(\Phi(y, t), t), \quad t \in [0, T],
\]

has a unique solution \( x := \Phi(y, t) \in \Gamma(t) \), which defines the Langrangian mapping \( \Phi : \Gamma_0 \to \Gamma(t) \).

The inverse mapping is given by \( \Phi^{-1}(x, t) := y \in \Gamma_0, \, x \in \Gamma(t) \). With the help of \( \Phi \), we define the bijection \( \Psi \) between \( \Gamma_0 \times [0, T] \), with \( \Gamma_0 := \Gamma(0) \), and the space-time manifold

\[
\mathcal{G} := \bigcup_{t \in (0, T)} \Gamma(t) \times \{ t \}, \quad \mathcal{G} \subset \mathbb{R}^4
\]

as follows

\[
\Psi : \Gamma_0 \times [0, T] \to \mathcal{G}, \quad \Psi(y, t) := (\Phi(y, t), t).
\]  

(2.6)

We assume \( \Psi \) is a \( C^2 \)-diffeomorphism between these manifolds.

For \( \Gamma(t) \), consider a signed distance function \( \phi(t) \) (positive in the exterior and negative in the interior of \( \Gamma(t) \)). Let \( \mathcal{O}_\delta(\mathcal{G}) \) be a tubulate \( \delta \)-neighborhood of \( \Gamma \):

\[
\mathcal{O}_\delta(\mathcal{G}) := \{ (x, t) \in \mathbb{R}^4 : |\phi(x, t)| \leq \delta \}.
\]

The above assumptions imply that for sufficiently small \( \delta > 0 \) it holds \( \phi \in C^2(\mathcal{O}_\delta(\mathcal{G})) \) and the normal projection onto \( \Gamma(t) \), \( \mathbf{p} : \mathcal{O}_\delta(\mathcal{G}) \to \Gamma(t) \) is well defined for each \( t \in [0, T] \). We fix such \( \delta \) and further often skip it in notation \( \mathcal{O}_\delta(\mathcal{G}) = \mathcal{O}_\delta \mathcal{G}(\mathcal{G}) \). Likewise, we shall write \( \mathcal{O}_\delta(\Gamma(t)) \) to denote a \( \delta \)-neighborhood of \( \Gamma(t) \) in \( \mathbb{R}^3 \) and \( \mathcal{O}(\Gamma(t)) = \mathcal{O}_0(\Gamma(t)) \) for \( \delta \) as above. For every fixed \( t \in [0, T] \), the gradient of \( \phi \) defines in \( \mathcal{O}(\Gamma(t)) \) normal direction to \( \Gamma(t) \) with \( \mathbf{n} = \nabla \phi \) being the outward normal vector on \( \Gamma(t) \).

For a smooth \( u \) defined on \( \mathcal{G} \), a function \( u^c \) denotes the extension of \( u \) to \( \mathcal{O}(\mathcal{G}) \) along spatial normal directions to the level-sets of \( \phi \), it holds \( \nabla u^c \cdot \nabla \phi = 0 \) in \( \mathcal{O}(\mathcal{G}) \), \( u^c = u \) on \( \mathcal{G} \), and \( u^c(x) = u^c(\mathbf{p}(x)) \) in \( \mathcal{O}(\mathcal{G}) \). The extension \( u^c \) is smooth once \( \phi \) and \( u \) are both smooth. Further, we use the same notation \( u \) for the function on \( \mathcal{G} \) and its extension to \( \mathcal{O}(\mathcal{G}) \).

Once a function \( u \) on \( \mathcal{G} \) is identified with its extension on \( \mathcal{O}(\mathcal{G}) \), one can write the surface differential operators arising in the model, in terms of tangential calculus:

\[
\nabla_\Gamma u = (\mathbf{I} - \mathbf{n} \times \mathbf{n}^T) \nabla u, \quad \text{div}_\Gamma \mathbf{w} = \text{tr} \left( (\mathbf{I} - \mathbf{n} \times \mathbf{n}^T) \nabla \mathbf{w} \right), \quad \Delta_\Gamma u = \text{div}_\Gamma \nabla_\Gamma u.
\]  

(2.7)

Furthermore, one can expand the intrinsic surface quantity \( \dot{u} \) in Eulerian terms:

\[
\dot{u} = \frac{\partial u}{\partial t} + \mathbf{w} \cdot \nabla u.
\]  

(2.8)
Identity (2.8) allows us to rewrite (2.5) as follows:
\[
\begin{align*}
\frac{\partial u}{\partial t} + \mathbf{w} \cdot \nabla u &= -\varepsilon^{-2}f(u) + \Delta_{\Gamma} u \quad \text{on} \quad \Gamma(t), \quad t \in (0,T], \\
\nabla u \cdot \nabla \phi &= 0 \quad \text{in} \quad \mathcal{O}(\Gamma(t))
\end{align*}
\]
subject to \(u = u_0\) on \(\Gamma(0)\). This formulation will be useful for the design of a finite element method in Section 5. We note that equalities (2.7)–(2.8) are valid for any smooth extension (not necessarily a normal one).

3. Asymptotic analysis. In this section, we study an asymptotic behaviour of \(u\) solving (2.5) when \(\varepsilon\) goes to zero. Our analysis follows the inner-outer expansion arguments, which are now standard for phase-field equations defined on Euclidean domains in \(\mathbb{R}^d\), \(d = 2, 3\), [3, 4, 35] and also has been used recently to study sharp interface limits of two phase-field models defined on surfaces [10, 30].

We assume \(t \geq t_0\) sufficiently large such that the separation of phases happened and \(u\) exhibits an inner layer (diffuse interface) of width \(O(\varepsilon)\). Consider the central line of the diffuse interface defined as the zero level of \(u\), \(\gamma(t) := \{x \in \Gamma(t) : u(x, t) = 0\}\). For all \(t \in (t_0, T)\) we assume that \(\gamma(t)\) is a smooth closed curve on \(\Gamma(t)\). The interior and exterior domains with respect to \(\gamma(t)\) are denoted by \(\Gamma^\pm(t) := \{x \in \Gamma(t) : \pm u(x, t) > 0\}\).

Outer expansion. Denote by \(u^\pm\) the order parameter restricted to \(\Gamma^\pm\). Following, e.g., [4] we assume that away from the interfacial layer around \(\gamma(t)\), both \(u^\pm\) can be expanded in the form
\[
u^\pm(x, t) = u_0^\pm(x, t) + \varepsilon u_1^\pm(x, t) + \cdots,
\]
with smooth \(u_0^\pm(x, t)\). Substituting (3.1) into (2.5) and using the Taylor expansion for \(f(u), f(u^\pm) = f(u_0^\pm) + \varepsilon f'(u_0^\pm) u_1^\pm + \cdots\), yield
\[
(\dot{u}_0^\pm(x, t) + \varepsilon \dot{u}_1^\pm(x, t) + \cdots) - \Delta_{\Gamma}(u_0^\pm(x, t) + \varepsilon u_1^\pm(x, t) + \cdots) + \varepsilon^{-2}(f(u_0^\pm) + \varepsilon f'(u_0^\pm) u_1 + \cdots) = 0.
\]
Considering the leading order term with respect to \(\varepsilon \to 0\) gives \(f(u_0^\pm) = 0\). Therefore, away from the layer it holds
\[
u_0^\pm(x, t) = \pm 1.
\]

Inner expansion. Denote by \(d_\gamma\) the signed geodesic distance on \(\Gamma(t)\) for any fixed \(t\), and \(\pm d_\gamma(x) > 0\) for \(x \in \Gamma^\pm\). Consider the inner layer \(U_\varepsilon(\gamma(t))\), which we define as an \(O(\varepsilon)\) neighborhood of \(\gamma(t)\): \(U_\varepsilon(\gamma(t)) := \{x \in \Gamma(t) : \|d_\gamma(x)\| \leq c_0 \varepsilon\}\), with sufficiently large \(c_0\), independent of \(\varepsilon\). We assume \(\varepsilon\) to be sufficiently small such that the geodesic closest point projection \(q(x) : U_\varepsilon(\gamma(t)) \to \gamma(t)\) is well-defined so that \((q(x), d_\gamma(x))\) is the local (time dependent) coordinate system in \(U_\varepsilon(\gamma(t))\). In \(U_\varepsilon(\gamma(t))\) the conormal directions are defined by the tangential vector field \(\mathbf{m} = \nabla_{\Gamma} d_\gamma\). For \(x \in \gamma(t)\), \(\mathbf{m}(x)\) is a unit conormal of \(\gamma(t)\) pointing into \(\Gamma^+\).

Following [4, 35], we introduce a fast variable in \(U_\varepsilon(\gamma(t))\) by re-scaling the coordinate in the conormal direction \(\xi = \frac{d_\gamma(x)}{\varepsilon}\), and represent \(u(x, t)\) as
\[
u(x, t) = \tilde{u}(x, \xi, t) \quad \text{for} \quad x \in U_\varepsilon(\gamma(t)),
\]
where \(\tilde{u}(t) : U_\varepsilon(\gamma(t)) \times (-c_0, c_0) \to \mathbb{R}\) is defined as \(\tilde{u}(y, \xi, t) := u(x, t)\) for \(x \in U_\varepsilon(\gamma(t))\) such that \(q(y) = q(x)\) and \(\xi = d_\gamma(x)\). Given the new variables we find the identities:
\[
\nabla_{\Gamma} u = \nabla_{\overline{\Gamma}} \tilde{u} + \varepsilon^{-1} \partial_\xi \tilde{u} \mathbf{m}, \quad \Delta_{\Gamma} u = \Delta_{\overline{\Gamma}} \tilde{u} + \varepsilon^{-2} \partial_{\xi \xi} \tilde{u} + \varepsilon^{-1} \partial_\xi \tilde{u} \Delta_{\overline{\Gamma}} d_\gamma,
\]
where for the second equality we used \(\mathbf{m} \cdot \nabla_{\overline{\Gamma}} \tilde{u} = 0\) and \(\text{div}_{\overline{\Gamma}} \mathbf{m} = \Delta_{\overline{\Gamma}} d_\gamma\). Denoting by \(\hat{\tilde{u}}\) the material derivative of \(\tilde{u}(y, \xi, t)\) we also compute
\[
\hat{\tilde{u}} = \hat{\tilde{u}} + \varepsilon^{-1} \partial_\xi \tilde{u} d_\gamma.
\]
We assume that \(\hat{\tilde{u}}\) in the layer can be expanded
\[
\hat{\tilde{u}}(x, \xi, t) = \hat{u}_0(x, \xi, t) + \varepsilon \hat{u}_1(x, \xi, t) + \cdots,
\]
with smooth $\tilde{u}_0, \tilde{u}_1, \ldots$. Substituting this in (2.5), using (3.4)–(3.5) and Taylor expansion for $f(\tilde{u})$, i.e. $f(\tilde{u}) = f(\tilde{u}_0) + \varepsilon f'(\tilde{u}_0) \tilde{u}_1 + \cdots$, we find that $O(\varepsilon^{-2})$ order terms give

$$-\partial_\xi \tilde{u}_0 + f(\tilde{u}_0) = 0.$$  

(3.6)

Accounting for $O(\varepsilon^{-1})$ order terms we obtain

$$\partial_\xi \tilde{u}_0 \left( \dot{d}_\gamma - \Delta_G d_\gamma \right) - 2\nabla_G d_\gamma \cdot \nabla_G (\partial_\xi \tilde{u}_0) - \partial_\xi \tilde{u}_1 + f'(\tilde{u}_0) \tilde{u}_1 = 0.$$  

(3.7)

To proceed we need conditions on $\tilde{u}_0$ for $\xi \to \infty$ (which can be allowed if $\varepsilon \to 0$).

**Matching conditions.** We now have a representation of the solution in the narrow layer around $\gamma(t)$ and another representation valid away from the interface. Following [4, 35] we consider matching conditions between these two representations. We formulate the conditions below, while details of derivation can be found in [13]. Denote $u_k^\pm(x, t) = \lim_{s \to \pm 0} u_k^\pm(x + sm, t)$ when $x \in \gamma(t)$ and $\varepsilon \to 0$, and similar we define $\nabla_G u_k^\pm(x, t)$ for $x \in \gamma(t)$. The matching conditions read:

$$\tilde{u}_0(x, \xi, t) = u_0^\pm(x, t), \quad \text{as } \xi \to \pm\infty, \ \varepsilon \xi \to 0$$  

(3.8)

$$\tilde{u}_1(x, \xi, t) = u_1^\pm(x, t) + \xi m \cdot \nabla_G u_0^\pm(x, t), \quad \text{as } \xi \to \pm\infty, \ \varepsilon \xi \to 0$$  

(3.9)

$$\partial_\xi \tilde{u}_1(x, \xi, t) = m \cdot \nabla_G u_0^\pm(x, t), \quad \text{as } \xi \to \pm\infty, \ \varepsilon \xi \to 0.$$  

(3.10)

From condition (3.8) and (3.2) it follows that

$$\lim_{\xi \to \pm\infty} \tilde{u}_0 = \pm 1.$$  

(3.11)

This and $\tilde{u}_0(x, 0, t) = 0$ supplies the equation (3.6) with necessary boundary conditions. For $f(\tilde{u}_0) = -\tilde{u}_0 + \tilde{u}_0^3$ it provides us with the unique solution

$$\tilde{u}_0(x, \xi, t) = \tanh(\xi/\sqrt{2}).$$

In particular, we see that $\tilde{u}_0$ does not depend on $(x, t)$. This simplifies equation (3.7) to

$$\partial_\xi \tilde{u}_0 \left( \dot{d}_\gamma - \Delta_G d_\gamma \right) - \partial_\xi \tilde{u}_1 + f'(\tilde{u}_0) \tilde{u}_1 = 0.$$  

We multiply the above identity by $\partial_\xi \tilde{u}_0$ and integrate it for $\xi \in (-\infty, \infty)$. This leads to

$$\sigma \left( \dot{d}_\gamma - \Delta_G d_\gamma \right) - \int_{-\infty}^\infty (\partial_\xi \tilde{u}_0) [\partial_\xi \tilde{u}_1 - f'(\tilde{u}_0) \tilde{u}_1] d\xi = 0.$$  

(3.12)

where $\sigma := \int_{-\infty}^\infty (\partial_\xi \tilde{u}_0)^2 d\xi$ is a positive constant that can be interpreted as interface tension coefficient. Now let us take a further look into matching conditions (3.8)–(3.10). The first one implies

$$f'(\tilde{u}_0) = f(\tilde{u}_0) = 0 \quad \text{for } \xi \to \pm\infty.$$  

Since $m \cdot \nabla_G u_0^\pm(x, t) = 0$, from (3.9) and (3.10) we also see that $|\tilde{u}_1|$ is bounded and $\partial_\xi \tilde{u}_1 = 0$ for $\xi \to \pm\infty$. Using these limit values for the integration by parts, we obtain

$$\int_{-\infty}^\infty \partial_\xi \tilde{u}_0 [\partial_\xi \tilde{u}_1 - f'(\tilde{u}_0) \tilde{u}_1] d\xi = \int_{-\infty}^\infty \partial_\xi \tilde{u}_0 \partial_\xi \tilde{u}_1 - \partial_\xi f(\tilde{u}_0) \tilde{u}_1 d\xi = \int_{-\infty}^\infty [\partial_\xi \tilde{u}_0 - f(\tilde{u}_0)] \partial_\xi \tilde{u}_1 d\xi = 0,$$

where for the last equality we use (3.6). Equation (3.12) reduces to

$$\dot{d}_\gamma - \Delta_G d_\gamma = 0.$$  

(3.13)

Consider the limiting interface $\gamma(t)$ as the zero level of the order-parameter as $\varepsilon \to 0$. Equation (3.13) for the signed distance function describes the dynamics of $\gamma(t)$ on the passively evolving material surface $\Gamma(t)$. The quantity $\Delta_G d_\gamma = \kappa_g$ is the geodesic curvature of $\gamma(t)$ on $\Gamma(t)$ satisfying that $\kappa_g(x)$ is positive when $\Gamma(t)$ is convex at $x$. While $\dot{d}_\gamma = 0$ corresponds to the passive evolution along material trajectories, $\dot{\gamma} = \kappa_g$ can be seen as an active evolution or a mean curvature type flow in the reference (Lagrangian) coordinates. The (tangential) geometric evolution of the sharp interface is defined by the conormal velocity of $\gamma(t)$ given by $m \cdot w - \kappa_g$.  

5
4. Weak formulation and well-posedness. Consider a slightly more general problem:

\[
\begin{align*}
\dot{u} + \alpha u - \Delta_G u + \varepsilon^{-2} f(u) &= 0 \quad \text{on } \Gamma(t), \\
\quad u(x, 0) &= u_0 \quad \text{for } x \in \Gamma(0),
\end{align*}
\]

with an \(L^\infty(G)\) function \(\alpha\), and let \(\alpha_* := \|\alpha\|_{L^\infty(G)}\). Following [40] we consider a modified double-well potential \(F\) such that for some \(M > 1\)

\[
F'(x) = f(x) = \begin{cases} (3M^2 - 1)x - 2M^3, & x > M, \\ x(x^2 - 1), & x \in [-M, M], \\ (3M^2 - 1)x + 2M^3, & x < -M. \end{cases}
\]

Function \(f(x)\) satisfies the following growth conditions with \(L = 3M^2 - 1\)

\[
|f(x)| \leq L|x|, \quad f(x)x \geq -x,
\]

and Lipschitz condition:

\[
-1 \leq \frac{f(x) - f(y)}{x - y} \leq L, \quad \forall x, y \in \mathbb{R}, \ x \neq y.
\]

Given our assumptions on the evolution of \(\Gamma(t)\), the scalar product

\[
(u, v)_0 = \int_0^T \int_{\Gamma(t)} uv \, dsdt
\]

induces a norm \(\| \cdot \|_0\) on \(L^2(G)\) equivalent to the standard \(L^2(G)\)-norm. Besides standard Lebesgue spaces \(L^q(G), 1 \leq q \leq \infty\), and Sobolev spaces \(H^k(G), k = 1, 2, \ldots,\), we need the following analogues of standard Bochner spaces:

\[
\begin{align*}
H &= \{u \in L^2(G) : \|\nabla_G u\|_0 < \infty\}, \quad \text{with } (u, v)_H = (u, v)_0 + (\nabla_G u, \nabla_G v)_0, \\
L_1^\infty &= \{u \in L^\infty(G) : \text{ess sup}_{t \in [0,T]} \|\nabla_G u\|_{L^2(\Gamma(t))} \leq \infty\}, \\
W &= \{u \in L_1^\infty : \hat{u} \in L^2(G)\}, \quad \|u\|_W^2 = \|u\|_{L_1^\infty}^2 + \|\hat{u}\|_{L^2(G)}^2.
\end{align*}
\]

From [33, 8] we know that \(H\) is a Hilbert space and smooth functions are everywhere dense in \(H\) and \(W\).

Exploiting the smoothness properties of the mapping \(\Psi\) between \(\Gamma_0 \times (0, T)\) and \(G\) one shows (cf. [33, 8]) that the following isomorphisms hold algebraically and topologically: \(H \cong L^2(0, T; H^1(\Gamma_0))\) and \(W \cong L^\infty(0, T; H^1(\Gamma_0)) \cap H^1(0, T; L^2(\Gamma_0)).\)

We consider the following weak formulation of (4.1): For \(u_0 \in H^1(\Gamma_0)\), find \(u \in W\) such that \(u(0) = u_0\) and

\[
(u, v)_0 + (\alpha u + \varepsilon^{-2} f(u), v)_0 + (\nabla_G u, \nabla_G v)_0 = 0, \quad \text{for all } v \in H.
\]

**Lemma 4.1.** The week formulation (4.6) is well posed.

**Proof.** A standard approach to the analysis of Allen-Cahn type equations solvability is based on the energy minimization principle, which does not hold in the case of equations posed in evolving domain. Hence we consider a different argument. For \(\dot{u} = \alpha u \circ \Psi \in L^\infty(0, T; H^1(\Gamma_0)) \cap H^1(0, T; L^2(\Gamma_0))\), \(v \in L^2(0, T; H^1(\Gamma_0))\) we re-write (4.6) in the reference cylinder \(\tilde{S} = \Gamma_0 \times (0, T)\):

\[
\int_0^T \int_{\Gamma_0} \{\dot{u} + \alpha \dot{u} + \varepsilon^{-2} f(\hat{u})\dot{v} + (\nabla_G F)^{-T} \nabla_G \dot{u} : (\nabla_G F)^{-T} \nabla_G \dot{v}\} \mu \, dsdt = 0,
\]

for all \(\dot{v} \in L^2(0, T; H^1(\Gamma_0))\). Here \(\mu \in C^1(\tilde{S}), \nabla_G \Psi \in C^1(\tilde{S})^{3 \times 3}\) are such that \(\mu > 0\) and \(\nabla_G \Psi (\nabla_G \Psi)^T\) is uniformly bounded on \(\tilde{S}\). Therefore, the problem (4.7) can be formulated to
fit an abstract framework from [38]: Find \( \hat{u} \in L^\infty(0,T; H^1(\Gamma_0)) \cap H^1(0,T; L^2(\Gamma_0)) \) such that 
\[
\dot{u}(0) = u_0 \in H^1(\Gamma_0) \quad \text{and} \quad M\ddot{u} + B\dot{u} + \gamma(\hat{u}) = 0 \quad \text{in} \quad H^{-1}(\Gamma_0) \quad \text{for a.e.} \quad t \in [0,T],
\]
where operators \( M \in \mathcal{L}(L^2(\Gamma_0)), B \in \mathcal{L}(H^1(\Gamma_0),H^{-1}(\Gamma_0)) \) and \( \gamma : H^1(\Gamma_0) \to L^2(\Gamma_0) \) are defined by the identities
\[
M\dot{\hat{u}} = \mu\hat{u}, \quad \langle B\dot{\hat{u}}, \phi \rangle = \int_0^T \langle \nabla \hat{\phi} \nabla \phi, \hat{\phi} \rangle - T \nabla \phi \mu d\hat{s}, \quad \gamma(\hat{u}) = (\alpha\hat{u} + \varepsilon^{-2} f(\hat{u}))\mu,
\]
for all \( \hat{u} \in L^2(\Gamma_0), \hat{u}, \phi \in H^1(\Gamma_0) \). It is easy to verify that \( M \) is positive definite, \( B \) is such that
\[
\langle Bv,v \rangle \geq \hat{c}_1 \|v\|^2_{H^1(\Gamma_0)} - \hat{c}_2 \|v\|^2_{L^2(\Gamma_0)}, \quad \text{with some} \quad \hat{c}_1 > 0, \quad \hat{c}_2 \geq 0,
\]
and \( \gamma \) is continuous and, thanks to (4.4),
\[
\|\gamma(v)\|^2_{L^2(\Gamma_0)} \leq \hat{C}_1 + \hat{C}_2 \|v\|^2_{H^1(\Gamma_0)} , \quad \text{with some} \quad \hat{C}_1 > 0, \quad \hat{C}_2 > 0,
\]
\[
(\gamma(v) - \gamma(w), v - w)_{L^2(\Gamma_0)} \geq -\hat{C}_0 \|v - w\|^2_{L^2(\Gamma_0)}, \quad \text{with some} \quad \hat{C}_0 > 0,
\]
for all \( v, w \in H^1(\Gamma_0) \).

Problem (4.8)–(4.10) is well posed ([38, Theorem 2.1]) and so is (4.6). \( \square \)

5. Discretization method. To set up a numerical method, one needs to define a time-stepping procedure, spatial discretization approach and a practical way of handling surface integrals and derivatives. The approach taken here benefits from the embedding of \( \Gamma(t) \) in \( \mathbb{R}^d \) for all \( t \in [0,T] \), which allows to use tangential calculus in an ambient (bulk) functional space (rather than computations in intrinsic time-dependent surface coordinates). The bulk space supports well-defined traces of functions on \( \Gamma(t) \) and functions from the bulk space are further approximated in a standard time-independent finite element space. Our time-stepping procedure exploits an observation made earlier in section 2.1 that a function on \( \Gamma(t) \) can be identified with its smooth extension to a neighborhood of the surface. Finally, the geometry representation is based on the implicit definition of \( \Gamma_h(t) \), an approximation of \( \Gamma(t) \), as a zero level of a finite element function. Altogether, this approach resembles the trace finite element method for partial differential equations on evolving surfaces introduced and analyzed in [34, 24] for the diffusion problem on \( \Gamma(t) \). The approach is also known as a hybrid FD in time – trace FEM in space, since a (standard) finite difference scheme is adopted for treating the time dependence and an unfitted finite element method is used in space.

We start with explaining the time-stepping method.

5.1. Time-stepping scheme. Consider a uniformly distributed time nodes \( t_n = n\Delta t, n = 0, \ldots, N \), with the uniform time step \( \Delta t = T/N \). It is crucial to assume that \( \Delta t \) is sufficiently small that
\[
\Gamma(t_n) \subset \mathcal{O}(\Gamma(t_{n-1})) \quad n = 1, \ldots, N.
\]
Recall that \( \mathcal{O}(\Gamma(t)) \) is a neighborhood of the surface, where the normal projection on \( \Gamma(t) \) is well defined, and so are the extensions of surface quantities.

Using the notation \( u^n \) for an approximation to \( u(t_n) \), and \( \phi^n = \phi(t_n) \), we consider the following semi-implicit first order method for the Eulerian formulation (2.9) of the Allen-Cahn surface problem:
\[
\begin{cases}
(1 + \beta_\varepsilon \Delta t) \frac{u^n - u^{n-1}}{\Delta t} + w^n \cdot \nabla u^n - \Delta r u^n = -\varepsilon^{-2} f(u^{n-1}) & \text{on} \quad \Gamma(t_n), \\
\nabla u^n \cdot \nabla \phi^n = 0 & \text{in} \quad \mathcal{O}(\Gamma(t_n)).
\end{cases}
\]
Here \( \beta_\varepsilon > 0 \) is a stabilization parameter as suggested in [40] to allow the explicit treatment of the non-linear part on the right-hand side of (5.2). This leads to a linear problem with respect to \( u^n \) on each time step. More important is that function \( u^{n-1} \) is well-defined on \( \Gamma(t_n) \) through its extension. Indeed, if one considers (5.2) with index shifted \( n \rightarrow n - 1 \), i.e. eq. (5.2) written for the previous
time step, then the second equation defines the extension of \(u^{n-1}\) to \(O(\Gamma(t_{n-1}))\) and because of (5.1) it defines an extension to \(\Gamma(t_n) \subset O(\Gamma(t_{n-1}))\). Therefore, all terms in (5.2) on the current step are well defined.

For a finite element method, we shall need the integral formulation of (5.2), where we enforce the second equation weakly, as a constraint: Any smooth \(u^n\) solving (5.2) satisfies

\[
\int_{\Gamma(t_n)} ((1 + \beta_n \Delta t)u^n - u^{n-1} + w_n \cdot \nabla u^n) v ds + \int_{\Gamma(t_n)} \nabla u^n \cdot \nabla v ds + \rho \int_{O(\Gamma(t_n))} (\nabla u^n \cdot \nabla \phi^n)(\nabla v \cdot \nabla \phi^n) dx = -\varepsilon^{-2} \int_{\Gamma(t_n)} f(u^{n-1})v ds,
\]

for all sufficiently smooth test functions \(v : O(\Gamma(t_n)) \rightarrow \mathbb{R}\). \(\rho > 0\) is an augmentation parameter for the normal extension condition.

We need the integration by parts identity:

\[
\int_{\Gamma(t)} (w \cdot \nabla u)v ds = \frac{1}{2} \int_{\Gamma(t)} (w_T \cdot \nabla \Gamma u - w_T \cdot \nabla \Gamma v) ds - \frac{1}{2} \int_{\Gamma(t)} (\text{div} w_T) uv ds
\]

for sufficiently smooth \(u, v\) such that \(n \cdot \nabla u = n \cdot \nabla v = 0\) (recall that \(n = \nabla \phi\) on \(\Gamma\)).

### 5.2. Finite element method.

To reduce the repeated use of generic but unspecified constants, further in the paper we write \(x \lesssim y\) to state that the inequality \(x \leq cy\) holds for quantities \(x, y\) with a constant \(c\), which is independent of the mesh parameters \(h, \Delta t\), time instance \(t_n\), and the position of \(\Gamma\) and \(\Gamma_h\) in the bulk mesh. Similar we give sense to \(x \gtrsim y\).

Assume a set of consistent subdivisions of \(\Omega\) into shape-regular tetrahedra. This constitutes a family of ambient triangulations \(\{T_h\}_{h > 0}\), with \(\max \text{diam}(T) \leq h\). For a fixed \(T_h\), denote by \(V_h\) the standard (bulk) time-independent finite element space of degree \(m \geq 1\),

\[
V_h = \{v_h \in C(\Omega) : v_h|_S \in P_m(S), \forall S \in T_h\}.
\]

Let \(\phi_h\) be a given continuous piecewise polynomial approximation (with respect to \(T_h\)) of \(\phi\) for all \(t \in [0, T]\), which satisfies

\[
\|\phi - \phi_h\|_{L^\infty(\Gamma(t))} + h\|\nabla(\phi - \phi_h)\|_{L^\infty(\Gamma(t))} \lesssim h^{q+1}, \quad \forall t \in [0, T],
\]

with some \(q \geq 1\). For this estimate to hold, we need to assume that the distance function \(\phi\) has the smoothness property \(\phi \in C^{q+1}(O(\Gamma))\). Following [23], we also assume that \(\nabla \phi_h(\mathbf{x}, t) \neq 0\) in \(O(\Gamma(t))\), \(t \in [0, T]\), and that \(\phi_h\) is sufficiently regular in time such that on every time interval \(I_n = [t_{n-1}, t_n]\) there holds

\[
\|\phi_h^{n-1} - \phi_h^n\|_{L^\infty(\Omega)} \lesssim \Delta t \|w \cdot n\|_{\infty, I_n},
\]

\[
\|\nabla \phi_h^{n-1} - \nabla \phi_h^n\|_{L^\infty(\Omega)} \lesssim \Delta t (\|w \cdot n\|_{\infty, I_n} + \|\nabla(w \cdot n)\|_{\infty, I_n}), \quad \text{for } n = 1, \ldots, N,
\]

where \(\phi_h^n(\mathbf{x}) = \phi_h(\mathbf{x}, t_n), \quad n = 0, \ldots, N,\) and \(\|v\|_{\infty, I_n} := \sup_{t \in I_n} \|v\|_{L^\infty(\Gamma(t))}\), for \(v\) defined on \(\Gamma(t)\).

We now introduce the “discrete” surfaces \(\Gamma_h^n\) as the zero level of \(\phi_h^n\),

\[
\Gamma_h^n := \{\mathbf{x} \in \mathbb{R}^3 : \phi_h^n(\mathbf{x}) = 0\}.
\]

Thanks to (5.6) it approximates the original surface \(\Gamma\) in the following sense

\[
\text{dist}(\Gamma_h^n, \Gamma(h)) = \max_{x \in \Gamma_h^n} |\phi^n(x)| = \max_{x \in \Gamma_h^n} |\phi^n(x) - \phi_h^n(x)| \leq \|\phi^n - \phi_h^n\|_{L^\infty(\Omega)} \lesssim h^{q+1}.
\]

Furthermore, \(n_h^n = \nabla \phi_h^n/|\nabla \phi_h^n|\), the normal vector to \(\Gamma_h^n\), and \(n^n = \nabla \phi^n\), the extended normal vector to \(\Gamma(t_n)\), satisfy for \(x \in \Gamma_h^n\)

\[
|n_h^n(x) - n^n(x)| \lesssim |\nabla \phi_h^n(x) - \nabla \phi^n(x)| \lesssim h^q.
\]
For practical reasons, the finite element method does not look for an extension of the discrete solution to the whole neighborhood $\mathcal{O}(\mathcal{G})$. Instead it provides an extension to a narrow band around $\Gamma_h^n$, which is defined as the union of tetrahedra on a $\delta_n$ distance from $\Gamma_h^n$ for each $n$, with
\begin{equation}
\delta_n := c_\delta \| w \cdot n \|_{\infty, J_n} \Delta t \tag{5.10}
\end{equation}
and $c_\delta \geq 1$, an $\mathcal{O}(1)$ mesh-independent constant. More precisely, we define the narrow band as
\begin{equation}
\mathcal{O}(\Gamma_h^n) = \bigcup \{ S : S \in \mathcal{T}_h : |\phi_h^n(x)| \leq \delta_n \text{ for some } x \in S \}. \tag{5.11}
\end{equation}
We also need a subdomain of $\mathcal{O}(\Gamma_h^n)$ only consisting of tetrahedra intersected by $\Gamma_h^n$,
\begin{equation}
\mathcal{O}_T(\Gamma_h^n) := \bigcup \{ S \in \mathcal{T}_h : S \cap \Gamma_h^n \neq \emptyset \}. \tag{5.12}
\end{equation}
Since $\text{dist}(\Gamma_h^n, \Gamma(t_n)) \lesssim h^{q+1}$, the narrow band width $\delta_n$ and $h$ can be assumed small enough such that
\begin{equation}
\mathcal{O}(\Gamma_h^n) \subset \mathcal{O}(\Gamma(t_n)). \tag{5.13}
\end{equation}
This implies the restriction on the time step of the form
\begin{equation}
\Delta t \leq c_0 (c_\delta \| w \cdot n \|_{\infty, J_n} - 1) = \mathcal{O}(1), \quad n = 1, \ldots, N, \tag{5.14}
\end{equation}
with some $c_0$ sufficiently small, but independent of $h$, $\Delta t$ and $n$. In turn, $c_\delta$ can be taken sufficiently large, but independent of $h$, such that
\begin{equation}
\mathcal{O}_T(\Gamma_h^n) \subset \mathcal{O}(\Gamma_h^{n-1}). \tag{5.15}
\end{equation}
This condition is the discrete analog of (5.1) and it is essential for the well-posedness of the finite element formulation below.

Next we define finite element spaces as restrictions of the time-independent bulk space $V_h$ on all tetrahedra from $\mathcal{O}(\Gamma_h^n)$:
\begin{equation}
V_h^n = \{ v \in C(\mathcal{O}(\Gamma_h^n)) : v \in P_m(S), \forall S \in \mathcal{T}_h, S \subset \mathcal{O}(\Gamma_h^n) \}, \quad m \geq 1. \tag{5.16}
\end{equation}
We further use $V_h^n$ as test and trial spaces in the integral formulation (5.3), where we use identity (5.4) and replace $\Gamma(t_n)$ by $\Gamma_h^n$, $\mathcal{O}(\Gamma(t_n))$ by $\mathcal{O}(\Gamma_h^n)$. The resulting FE formulation reads: For a given $u_h^n \in V_h^n$ find $w_h^n \in V_h^n$, $n = 1, \ldots, N$, satisfying
\begin{equation}
\int_{\Gamma_h^n} \left\{ (1 + \beta_s \Delta t) \frac{u_h^n - u_h^{n-1}}{\Delta t} v_h + \frac{1}{2} (w_T^n \cdot \nabla \Gamma_h^n) u_h^n v_h - w_T^n \cdot \nabla \Gamma_h^n v_h u_h^n - (\text{div}_{\Gamma_h^n} w_T^n) u_h^n v_h \right\} ds_h \\
+ \int_{\Gamma_h^n} \nabla \Gamma_h^n u_h^n \cdot \nabla \Gamma_h^n v_h ds_h + \rho_n \int_{\Gamma_h^n} (n_h^n \cdot \nabla w_h^n)(n_h^n \cdot \nabla v_h)(dx = -\varepsilon^{-2} \int_{\Gamma_h^n} f(u_h^{n-1}) v_h ds_h, \tag{5.17}
\end{equation}
for all $v_h \in V_h^n$. Here $n_h = \nabla \phi_h^n / |\nabla \phi_h^n|$ in $\mathcal{O}(\Gamma_h^n)$, $\rho_n > 0$ is a parameter, $w_T^n(x) = w(p^n(x))$ is a lifted data on $\Gamma_h^n$ from $\Gamma(t_n)$. The terms involving $u_h^{n-1}$ are well-defined thanks to condition (5.13). With suitable restrictions on problem parameters the last term on the left-hand side of (5.17) ensures the whole bilinear form is elliptic on $V_h^n$; see (6.11). Therefore, on each time step we obtain a FE solution defined in $\mathcal{O}(\Gamma_h^n)$ (not just on $\Gamma_h^n$ and this can be seen as an implicit extension procedure). As discussed in many places in the literature, see, e.g., [24], this term also stabilizes the problem algebraically, i.e. the resulting systems of algebraic equations are well-conditioned independent on how the surface $\Gamma_h$ cuts through the ambient triangulation.

**Remark 5.1 (Numerical integration).** The discrete surface $\Gamma_h^n$ is described implicitly via the zero-level of a piecewise polynomial level set function. In general, it is a non-trivial task to obtain a parameterized representation of $\Gamma_h^n$, which would allow for a straightforward application of numerical quadrature rules. On simplices and in the low order case where $\phi_h^n$ is a piecewise linear approximation of the level set function $\phi^n$ ($q = 1$ in (5.6)), an explicit reconstruction of $\Gamma_h^n$ is easily available, cf. e.g. [27]. However, the higher order case $q > 1$ is more involved and requires special approaches for the construction of quadrature rules. We do not extend this discussion here but refer to the literature instead, cf. [12, 22, 14, 29, 37, 42].
6. Analysis of the finite element method. In this section we address stability and error analysis of the finite element formulation (5.15). For a proper control of the geometric error, the analysis requires the following mild restriction on the mesh step,

\[ h^{2q} \lesssim \Delta t. \]  

(6.1)

We recall that \( q \geq 1 \) is the degree of geometry approximation from (5.6).

We shall need the following two Lemmas from [24]. The result of the first lemma allows the control of the \( L^2 \) norm of \( v_h \in V^n_h \) in the narrow band by its \( L^2 \) norm on \( \Gamma_h \) and a term similar to the normal volume stabilization in (5.15). While the second lemma provides control over the \( L^2 \) norm of the extension of a FE function on \( \Gamma^n_h \) by its values on \( \Gamma^n_{h-1} \). That lemma is essential for applying a Gronwall type argument later.

**Lemma 6.1.** Assume conditions (5.10) and (5.12) are satisfied, then for any \( v_h \in V^n_h \) it holds

\[ \|v_h\|_{\mathcal{O}(\Gamma^n_h)}^2 \lesssim (\delta_n + h)^2 \|v_h\|_{\Gamma^n_h}^2 + (\delta_n + h)^2 \|n_h^R \cdot \nabla v_h\|_{\mathcal{O}(\Gamma^n_h)}^2. \]

(6.2)

**Lemma 6.2.** In addition to (5.10) and (5.12) assume (6.1) is satisfied, then for any \( v_h \in V^n_{h-1} \) it holds

\[ \|v_h\|_{\Gamma^n_h}^2 \leq (1 + c_1 \Delta t\|v_h\|_{\Gamma^{n-1}_h}^2 + c_2 \delta_n^{-1} (\delta_n - h)^{-1} \|v_h\|_{\Gamma^{n-1}_h}^2 \|n_h^R \cdot \nabla v_h\|_{\mathcal{O}(\Gamma^{n-1}_h)}^2, \]

(6.3)

for some \( c_1 \) and \( c_2 \) independent of \( h, \Delta t \) and \( n \).

Examination of the proof from [24] reveals that Lemma 6.2 holds if \( V^n_{h-1} \) is replaced by any finite dimension subspace of \( H^1(\mathcal{O}(\Gamma^n_{h-1})) \) that supports inverse inequality \( \|\nabla v_h\|_S \lesssim h^{-1} \|v_h\|_S \), for \( S \in T_h, S \in \mathcal{O}(\Gamma^n_{h-1}) \). We need this observation later in the paper.

6.1. Stability analysis. In addition to (5.12), we need another \( O(1) \) restriction on the time step:

\[ \Delta t \leq (4\xi_h)^{-1} \]  

(6.4)

with \( \xi_h := \max_{n=0,\ldots,N} \| \text{div}_{\Gamma_h} w^n_T\|_{\infty,\Gamma^n_h} \).

From the definition of \( \xi_h \), smoothness of \( w \), and geometry approximation condition (5.6), it follows that

\[ \xi_h \lesssim 1. \]

(6.5)

The normal volume stabilization parameter \( \rho_n \) in (5.15) should be chosen to satisfy:

\[ \rho_n \geq C_\rho (\delta_n + h)^{-1} \]

(6.6)

with some sufficiently large, but independent of \( \Delta t \) and \( h \), constant \( C_\rho > 0 \). Recalling that \( \delta_n \lesssim \Delta t \) (see (5.10)) we see that (6.6) leads an \( O((\Delta t + h)^{-1}) \) lower bound on \( \rho_n \). For the stabilization parameter \( \beta_n \) we assume

\[ \beta_n \geq 2\xi_h + \varepsilon^{-2}L + 1. \]

(6.7)

With the help of (5.10) and (6.6) we obtain the inequality

\[ c_2 \delta_n^{-1} (\delta_n - h)^{-1} \leq c_2\beta_n \|w \cdot n\|_{\infty, T^n_{h-1}} \Delta t C_{\rho^{-1}} \rho_n^{-1}. \]

Using this, estimate (6.3) for \( C_\rho \) large enough yields

\[ \|v_h\|_{\Gamma^n_h}^2 \leq (1 + c_1 \Delta t\|v_h\|_{\Gamma^{n-1}_h}^2 + \rho_n^{-1} \Delta t \|n_h^R \cdot \nabla v_h\|_{\mathcal{O}(\Gamma^{n-1}_h)}^2 \]  

(6.8)

\[ \forall v_h \in V^n_{h-1}. \]

For the notation convenience, we now introduce the bilinear form,

\[ a_n(u, v) := \frac{1}{2} \int_{\Gamma^n_h} \left( (w^n_T \cdot \nabla_{\Gamma_h} u)v - (w^n_T \cdot \nabla_{\Gamma_h} v)u - (\text{div}_{\Gamma_h} w^n_T)uv \right) ds \]

(6.9)

\[ + \int_{\Gamma^n_h} (\nabla_{\Gamma_h} u) \cdot (\nabla_{\Gamma_h} v) ds + \rho_n \int_{\mathcal{O}(\Gamma^n_h)} (n_h^R \cdot \nabla u)(n_h^R \cdot \nabla v) dx. \]
for $u, v \in H^1(\Omega_h^n)$. Because of obvious cancellations, $a_n(v_h, v_h)$ satisfy the lower bound:

$$a_n(v_h, v_h) \geq \|\nabla u_h \cdot v_h\|_{\Gamma_h}^2 - \xi_h\|v_h\|_{\Gamma_h}^2 + \rho_n\|\nabla u_h\|_{\Omega_h^n}^2, \quad \forall v_h \in V_h^n. \tag{6.10}$$

The low bound (6.10) and condition (6.4) imply that the bilinear form on the left-hand side of (5.15) is positive definite,

$$\int_{\Gamma_h^n} \frac{1 + \beta_n \Delta t}{\Delta t} v_h^2 \, ds + a_n(v_h, v_h) \geq \frac{1 + 2\beta_n \Delta t}{2\Delta t} \|v_h\|_{\Gamma_h^n}^2 + \|\nabla u_h \cdot v_h\|_{\Omega_h^n}^2 + \rho_n\|\nabla u_h\|_{\Omega_h^n}^2. \tag{6.11}$$

From (6.2) it follows that the square root of the right-hand side in (6.11) defines a norm on $V_h^n$. Hence, due to the Lax-Milgram lemma, the problem in each time step of (5.15) is well-posed.

We next derive an a priori estimate for the finite element solution to (5.15).

**Theorem 6.3.** Assume conditions (5.10), (5.12), (6.1), (6.4), (6.6), and (6.7), then the solution of (5.15) satisfies the following stability estimate:

$$\|u_h^n\|_{\Gamma_h^n}^2 + \Delta t\varepsilon^{-2} \int F(u_h^n)ds_h + \Delta t \sum_{k=1}^{n} \left( \|\nabla u_h^n\|_{\Gamma_h^n}^2 + \Delta t \rho_n \|\nabla u_h^n\|_{\Omega_h^n}^2 \right) \leq c_0, \quad k = 1, \ldots, N, \tag{6.12}$$

where $c_0$ is independent of $\Delta t$, $h$, $n$ and position of $\Gamma_h$ in the mesh, but depends on $u_0$, $\varepsilon$, and $M$.

**Proof.** We test (5.15) with $v_h = u_h^n$ to arrive at the equality

$$\int_{\Gamma_h^n} \frac{1 + \beta_n \Delta t}{2\Delta t} (\|u_h^n\|_{\Gamma_h^n}^2 + \|u_h^n - u_h^{n-1}\|_{\Gamma_h^n}^2) + a_n(u_h^n, u_h^n) = \frac{1 + \beta_n \Delta t}{2\Delta t} \|u_h^{n-1}\|_{\Gamma_h^n}^2 - \varepsilon^{-2} \int_{\Gamma_h^n} f(u_h^{n-1})u_h^n \, ds_h.$$

From the Taylor expansion we get

$$-\int_{\Gamma_h^n} f(u_h^{n-1})u_h^n \, ds_h = \int_{\Gamma_h^n} F(u_h^{n-1}) - F(u_h^n) \, ds_h - \int_{\Gamma_h^n} f(u_h^{n-1})u_h^{n-1} \, ds_h + \int_{\Gamma_h^n} \frac{f(c)}{2} (u_h^n - u_h^{n-1})^2 \, ds_h \tag{6.13}$$

with some $c \in C(\Gamma_h^n)$. We bound $a_n(u_h^n, u_h^n)$ from below through (6.10) and further use (4.4), (4.5), (6.8), and (6.13) to arrive at

$$(1 + \Delta t(\beta_n - 2\xi_h))\|u_h^n\|_{\Gamma_h^n}^2 + 2\Delta t\|\nabla u_h^n\|_{\Gamma_h^n}^2 + 2\Delta t\rho_n \|\nabla u_h^n\|_{\Omega_h^n}^2 + 2\Delta t\varepsilon^{-2} \int_{\Gamma_h^n} F(u_h^n) \, ds_h$$

$$\leq (1 + \Delta t(\beta_n - 2\varepsilon^{-2})) \left( (1 + c\Delta t)\|u_h^{n-1}\|_{\Gamma_h^{n-1}}^2 + \Delta t\rho_{n-1} \|\nabla u_h^{n-1}\|_{\Omega_h^{n-1}}^2 \right) + 2\Delta t\varepsilon^{-2} \int_{\Gamma_h^n} F(u_h^{n-1}) \, ds_h$$

$$+ 2\Delta t\varepsilon^{-2} \int_{\Gamma_h^n} F(u_h^{n-1}) \, ds_h - (1 + \Delta t(\beta_n - 2\varepsilon^{-2}))\|u_h^n - u_h^{n-1}\|_{\Gamma_h^n}^2. \tag{6.14}$$

Using (6.7) simplifies the above estimate to

$$\|u_h^n\|_{\Gamma_h^n}^2 + 2\Delta t\|\nabla u_h^n\|_{\Gamma_h^n}^2 + 2\Delta t\rho_n \|\nabla u_h^n\|_{\Omega_h^n}^2 + 2\Delta t\varepsilon^{-2} \int_{\Gamma_h^n} F(u_h^n) \, ds_h$$

$$\leq (1 + c\Delta t) \left( \|u_h^{n-1}\|_{\Gamma_h^{n-1}}^2 + \Delta t\rho_{n-1} \|\nabla u_h^{n-1}\|_{\Omega_h^{n-1}}^2 \right) + 2\Delta t\varepsilon^{-2} \int_{\Gamma_h^n} F(u_h^{n-1}) \, ds_h, \tag{6.15}$$

where the constant $c$ is independent of $h$, $\Delta t$ and $n$.

We further estimate the $F$-term on the right-hand side employing Lemma 6.2 (see also the comment after the lemma) and the elementary inequality $|\sqrt{F(x)}_x| \leq C = 2M$ for almost all $x \in \mathbb{R}$:

$$\int_{\Gamma_h^n} F(u_h^{n-1}) \, ds_h = \|\sqrt{F(u_h^{n-1})}\|_{\Gamma_h^n}^2$$

$$\leq (1 + c\Delta t) \|\sqrt{F(u_h^{n-1})}\|_{\Gamma_h^{n-1}}^2 + c_2\Delta t \|\nabla u_h^{n-1}\|_{\Omega_h^{n-1}}^2 \|\sqrt{F(u_h^{n-1})}\|_{\Omega_h^{n-1}}^2$$

$$\leq (1 + c\Delta t) \int_{\Gamma_h^{n-1}} F(u_h^{n-1}) \, ds_h + c_3\Delta t \|\nabla u_h^{n-1}\|_{\Omega_h^{n-1}}^2 \|\sqrt{F(u_h^{n-1})}\|_{\Omega_h^{n-1}}^2$$

11
with $c_2$ and $c_3$ independent of problem parameters. Substituting this into (6.15) we obtain the estimate

$$
\|u_h^n\|_{1,h}^2 + 2\Delta t \|\nabla_h u_h^n\|_{1,h}^2 + 2\Delta t \rho_n \|n_h^n \cdot \nabla u_h^n\|_{C(\Gamma_h^n)}^2 + 2\Delta t \varepsilon^{-2} \int_{\Gamma_h^n} F(u_h^n) \, ds_h
$$

\leq (1 + c \Delta t) \left( \|u_h^{n-1}\|_{1,h-1}^2 + 2\Delta t \rho_{n-1} \|n_h^{n-1} \cdot \nabla u_h^{n-1}\|_{C(\Gamma_h^{n-1})}^2 + 2\Delta t \varepsilon^{-2} \int_{\Gamma_h^{n-1}} F(u_h^{n-1}) \, ds_h \right),

with some $c$ independent of $h$, $\Delta t$ and $n$. Applying discrete Gronwall inequality proves the theorem. \qed

Now we are ready to derive an error estimate in the energy norm. The proof of the error estimate combines the arguments we used for stability analysis in section 6.1 with geometric and interpolation error estimates. The geometric and interpolation error estimates are applied at each time instance $t_n$ for ‘stationary’ surfaces $\Gamma_h^n$ and so the existing analysis (cf. [36, 31]) is of help. We start with consistency estimate for (5.15).

**6.2. Consistency estimate.** While stability analysis dictated us the lower bound (6.6) for $\rho_n$, we assume a similar upper bound for the rest of section 6:

$$
\rho_n \lesssim (h + \delta_n)^{-1}. \tag{6.16}
$$

Substituting in (5.15) $u^n = u(t_n)$ for the smooth solution $u(t)$ of (2.9) we obtain

$$
\int_{\Gamma_h^n} (1 + \beta_2 \Delta t) \left( \frac{u^n - u^{n-1}}{\Delta t} \right) v_h \, ds_h + a_n(u^n, v_h) + \varepsilon^{-2} \int_{\Gamma_h^n} f(u^{n-1}) v_h \, ds = \mathcal{E}_C^n(v_h), \quad \forall v_h \in V_h^n, \tag{6.17}
$$

with $\mathcal{E}_C^n(v_h)$ collecting consistency terms due to geometric errors, time derivative approximation and nonlinear term, i.e.

$$
\mathcal{E}_C^n(v_h) = \int_{\Gamma_h^n} (1 + \beta_2 \Delta t) \left( \frac{u^n - u^{n-1}}{\Delta t} \right) v_h \, ds_h - \int_{\Gamma(t_n)} u_t(t_n) v_h^f \, ds
$$

$$
+ \rho_n \int_{C(\Gamma_h^n)} ((n_h^n - n^n) \cdot \nabla u^n)(n_h^n \cdot \nabla v_h) \, dx
$$

$$
+ \frac{1}{2} \int_{\Gamma_h^n} \mathbf{w}_T \cdot \nabla_{\Gamma_h^n} u^n v_h - \mathbf{w}_T \cdot \nabla_{\Gamma_h^n} v_h u^n \, ds_h - \frac{1}{2} \int_{\Gamma_h^n} \mathbf{w} \cdot \nabla u^n v_h^f - \mathbf{w} \cdot \nabla v_h^f u^n \, ds
$$

$$
+ \frac{1}{2} \int_{\Gamma(t_n)} \text{div}_{\Gamma}(\mathbf{w}_T) u^n v_h^f \, ds - \frac{1}{2} \int_{\Gamma_h^n} \text{div}_{\Gamma_h}(\mathbf{w}_T^n) u^n v_h \, ds_h
$$

$$
+ \int_{\Gamma_h^n} \nabla_{\Gamma_h} u^n \cdot \nabla_{\Gamma_h} v_h \, ds - \int_{\Gamma(t_n)} \nabla_T u^n \cdot \nabla_T v_h^f \, ds
$$

$$
+ \varepsilon^{-2} \int_{\Gamma(t_n)} f(u^{n-1}) v_h \, ds_h - \varepsilon^{-2} \int_{\Gamma(t_n)} f(u^n) v_h^f \, ds,
$$

where $v_h^f$ is the lifting of $v_h$ to $\Gamma(t_n)$ as defined in section 2.1. An estimate for consistency terms is given in the following lemma.

**Lemma 6.4.** Assume $u \in W^{2,\infty}(\mathcal{G})$, then consistency error has the bound

$$
|\mathcal{E}_C^n(v_h)| \lesssim (\Delta t + h^q) \|u\|_{W^{2,\infty}(\mathcal{G})} \left( \|v_h\|_{\Gamma_h^n} + \|\nabla_{\Gamma_h} v_h\|_{\Gamma_h^n} + \rho_n \|n_h^n \cdot \nabla v_h\|_{C(\Gamma_h^n)} \right). \tag{6.18}
$$
Proof. The required estimate for $I_1, \ldots, I_4$ is found in [24]. The last term $I_5$ gets estimated as
\[
\varepsilon^2 |I_5| = \left| \int_{\Gamma_h^s} (f(u^{n-1}) - f(u^n)) v_h \, ds_h + \int_{\Gamma_h^s} f(u^n) v_h \, ds_h - \int_{\Gamma_h^{s+1}} f(u^n) v_h^e \, ds \right|
\leq L \int_{\Gamma_h^s} \left| (u^{n-1} - u^n) v_h \right| \, ds_h + \left| \int_{\Gamma_h^s} f(u^n)(1 - \mu_h) v_h \, ds_h \right|
\leq L \Delta t \|u_t\|_{L^\infty(O(\mathcal{G}))} \|v_h\|_{\Gamma_h^s} + L \|u\|_{L^\infty(O(\mathcal{G}))} h^{q+1} \|v_h\|_{\Gamma_h^s} \lesssim \mu_h \|u\|_{W^{2,\infty}(\mathcal{G})} \|v_h\|_{\Gamma_h^s}.
\]
Here we have used $\mu_h = \frac{ds(p(x))}{\Delta x}$, $x \in \Gamma_h^s$, with $\|1 - \mu_h\|_{\infty, \Gamma_h^s} \leq h^{q+1}$ (cf. [36]).

6.3. Error estimate in the energy norm. Denote the error function by $E^n = u^n - u^n_h$, $E^n \in H^1(\Omega(\Gamma^n_h))$. From (5.15) and (6.17) we get the error equation, for $v_h \in V^n_h$:
\[
\int_{\Gamma_h^s} (1 + \beta_s \Delta t) \left( \frac{e^n - e^{n-1}}{\Delta t} \right) v_h \, ds + a_n(e^n, v_h) + \varepsilon^2 \int_{\Gamma_h^s} (f(u^{n-1}) - f(u^n)) v_h \, ds = \mathcal{E}_T^n(v_h) + \mathcal{E}_V^n(v_h). \tag{6.19}
\]
We let $u^n_T \in V^n_h$ be a nodal interpolant for $u^n$ in $O(\Gamma^n_h)$ that is assumed sufficiently smooth so that the interpolation is well-defined. Following standard lines of argument, we split $E^n$ into finite element and approximation parts,
\[
E^n = (u^n - u^n_T) + (u^n_T - u^n_h).
\]
Equation (6.19) yields, for any $v_h \in V^n_h$,
\[
\int_{\Gamma_h^s} (1 + \beta_s \Delta t) \left( \frac{e^n - e^{n-1}}{\Delta t} \right) v_h \, ds + a_n(e^n, v_h) + \varepsilon^2 \int_{\Gamma_h^s} (f(u^{n-1}) - f(u^n)) v_h \, ds = \mathcal{E}_T^n(v_h) + \mathcal{E}_V^n(v_h), \tag{6.20}
\]
with the interpolation term
\[
\mathcal{E}_T^n(v_h) = -(1 + \beta_s \Delta t) \int_{\Gamma_h^s} \left( \frac{e^n - e^{n-1}}{\Delta t} \right) v_h \, ds_h - a_n(e^n, v_h) + \varepsilon^2 \int_{\Gamma_h^s} (f(u^{n-1}) - f(u^n)) v_h \, ds_h.
\]
An estimate for interpolation terms is given in the following lemma. Further we assume $\mathcal{G}$ sufficiently smooth to support functions from $W^{m+1,\infty}(\mathcal{G})$.

Lemma 6.5. Assume $u \in W^{m+1,\infty}(\mathcal{G})$, then it holds
\[
\|\mathcal{E}_T^n(v_h)\| \lesssim h^m \|u\|_{W^{m+1,\infty}} \|v_h\|_{\Gamma_h^s}. \tag{6.21}
\]

Proof. We only need to estimate the third term of $\mathcal{E}_T^n(v_h)$. The required bound for other terms is given in [24]. We make use of the following local trace inequality, cf. [18, 36, 17]:
\[
\|v\|_{S \cap \Gamma^s_h} \leq c(h^{-\frac{1}{2}} \|v\|_S + h^\frac{1}{2} \|\nabla v\|_S), \quad v \in H^1(S), \quad S \in \mathcal{T}^s_h, \tag{6.22}
\]
with some $c$ independent of $v$, $T$, $h$, and position of $\Gamma^s_h$ in $S$. We need interpolation properties of polynomials and their traces [15, 36]:
\[
\|v^e - v_I\|_{\mathcal{C}^1(\Gamma^s_h)} + h \|\nabla (v^e - v_I)\|_{\mathcal{C}^1(\Gamma^s_h)} \lesssim h^{m+1} \|v^e\|_{H^{m+1}(\mathcal{C}^1(\Gamma^s_h))} \quad \text{for } v \in H^{m+1}(\Gamma^s_h). \tag{6.23}
\]
With the help of (4.4), (6.22), and (6.23) we estimate
\[
\left| \int_{\Gamma_h^s} (f(u^{n-1}) - f(u^n)) v_h \, ds \right| \leq L \int_{\Gamma_h^s} \left| (u^{n-1} - u^n) v_h \right| \, ds \leq L \|e^{n-1}\|_{\Gamma_h^s} \|v_h\|_{\Gamma_h^s}
\lesssim h^{-\frac{1}{2}} \left( \|e^{n-1}\|_{\mathcal{C}^1(\Gamma^s_h)} + h \|\nabla e^{n-1}\|_{\mathcal{C}^1(\Gamma^s_h)} \right) \|v_h\|_{\Gamma_h^s} \lesssim h^{-\frac{1}{2}} \left( h^{m+1} \|u\|_{H^{m+1}(\mathcal{C}^1(\Gamma^s_h))} \right) \|v_h\|_{\Gamma_h^s}
\lesssim h^{-\frac{1}{2}} \left( h^{m+\frac{1}{2}} \|u\|_{W^{m+1,\infty}(\mathcal{G})} \right) \|v_h\|_{\Gamma_h^s} \lesssim h^{m+1} \|u\|_{W^{m+1,\infty}(\mathcal{G})} \|v_h\|_{\Gamma_h^s}.
\]
Now we are prepared to prove the main result of the paper. Let \( u^n_h = u^n \in V^n_h \) be a nodal interpolant to \( u^0 \in \mathcal{O}(\Gamma_h^0) \).

**Theorem 6.6.** Assume (5.6)–(5.7b), (5.10), (5.12), (6.1), (6.4), (6.6), (6.7), and (6.16). Solution \( u \) to (2.5) is such that \( u \in W^{m+1,\infty}(\mathcal{G}) \). For \( u^n_h, n = 1, \ldots, N \), the finite element solution of (5.15), \( u^n = u(t_n) \), and the error function \( E^n = u^n_h - u^n \) the following estimate holds:

\[
\|E^n\|_{L^2(\Gamma_h^n)}^2 + \Delta t \sum_{k=1}^n \|\nabla \Gamma_h^n / \Gamma_h^n\|_{L^2(\Gamma_h^n)}^2 \leq \exp(c(t_n)) \|u\|_{W^{m+1,\infty}(\mathcal{G})}^2 (\Delta t^2 + h^2 \min(m, a)),
\]

(6.24)

with \( c \) independent of \( h, \Delta t, n \) and the position of the surface in the background mesh.

**Proof.** The arguments largely repeat those used to show the stability result in Theorem 6.3 and involve estimates from Lemmas 6.4 and 6.5 to bound the arising right-hand side terms. We set \( v_h = 2\Delta t e^n_h \) in (6.20). This gives

\[
(1 + \beta_n \Delta t) \left( \|e^n_h\|_{L^2(\Gamma_h^n)}^2 - \|e^{n-1}_h\|_{L^2(\Gamma_h^n)}^2 + \|e^n_h - e^{n-1}_h\|_{L^2(\Gamma_h^n)}^2 \right) + 2\Delta t \tau_n(e^n_h, e^n_h)
+ 2\varepsilon^2 \Delta t \int_{\Gamma_h^n} (f(u^n_{t-1}) - f(u^{n-1}_h)) e^n ds = 2\Delta t (E^n(e^n_h) + E^n(e^n_h)).
\]

The nonlinear term is estimated using (4.5):

\[
2 \int_{\Gamma_h^n} (f(u^n_{t-1}) - f(u^{n-1}_h)) e^n ds \leq 2 \int_{\Gamma_h^n} L|e^{n-1}_h - e^n_h| ds \leq L(\|e^{n-1}_h\|_{L^2(\Gamma_h^n)} + \|e^n_h\|_{L^2(\Gamma_h^n)}).
\]

Dropping out the third term, using the lower bound (6.10) for \( a_n \) and applying (6.8) to bound \( \|e^{n-1}_h\|_{L^2(\Gamma_h^n)} \) yields

\[
(1 + (\beta_n - \varepsilon^2 L) \Delta t) \|e^n_h\|_{L^2(\Gamma_h^n)}^2 + 2\Delta t \|\nabla \Gamma_h^n / \Gamma_h^n\|_{L^2(\Gamma_h^n)}^2 + 2\Delta t \tau_n \|n_h^n \cdot \nabla e^n_h\|_{L^2(\Gamma_h^n)}^2 + 2\Delta t (E^n(e^n_h) + E^n(e^n_h))
\]

\[
\leq (1 + (\beta_n - \varepsilon^2 L) \Delta t)(1 + c_1 \Delta t) \|e^{n-1}_h\|_{L^2(\Gamma_h^n)}^2 + \rho_n^{-1} \Delta t \|n_h^n \cdot \nabla e^{n-1}_h\|_{L^2(\Gamma_h^n)}^2.
\]

(6.25)

To estimate the interpolation and consistency terms, we apply Young’s inequality to the right-hand sides of (6.18) and (6.21) yielding

\[
2\Delta t E^n(e^n_h) \leq c \Delta t (\Delta t^2 + h^{2q}) \|u\|_{W^{q+1,\infty}(\mathcal{G})}^2 + \frac{\Delta t}{2} \left( \|e^n_h\|_{L^2(\Gamma_h^n)}^2 + \|\nabla \Gamma_h^n / \Gamma_h^n - \nabla u^n\|_{L^2(\Gamma_h^n)}^2 \right),
\]

\[
2\Delta t E^n(e^n_h) \leq c \Delta t \|u\|_{W^{m+1,\infty}(\mathcal{G})}^2 + \frac{\Delta t}{2} \left( \|e^n_h\|_{L^2(\Gamma_h^n)}^2 + \|\nabla \Gamma_h^n / \Gamma_h^n - \nabla u^n\|_{L^2(\Gamma_h^n)}^2 \right),
\]

with a constant \( c \) independent of \( h, \Delta t, n \) and of the position of the surface in the background mesh. By substituting above estimates in (6.25) we get

\[
(1 + (\beta_n - \varepsilon^2 L - 1) \Delta t) \|e^n_h\|_{L^2(\Gamma_h^n)}^2 + \Delta t \|\nabla \Gamma_h^n / \Gamma_h^n\|_{L^2(\Gamma_h^n)}^2 + \rho_n \Delta t \|n_h^n \cdot \nabla e^n_h\|_{L^2(\Gamma_h^n)}^2
\]

\[
\leq (1 + (\beta_n - \varepsilon^2 L) \Delta t)(1 + c_1 \Delta t) \|e^{n-1}_h\|_{L^2(\Gamma_h^n)}^2 + \rho_n^{-1} \Delta t \|n_h^n \cdot \nabla e^{n-1}_h\|_{L^2(\Gamma_h^n)}^2 + c \Delta t \|u\|_{W^{m+1,\infty}(\mathcal{G})}^2 (\Delta t^2 + h^{2q} + h^{2m}).
\]

(6.26)

Using lower bound (6.7) for \( \beta_n \) leads to

\[
\|e^n_h\|_{L^2(\Gamma_h^n)}^2 + \Delta t \|\nabla \Gamma_h^n / \Gamma_h^n\|_{L^2(\Gamma_h^n)}^2 + \Delta t \rho_n \|n_h^n \cdot \nabla e^n_h\|_{L^2(\Gamma_h^n)}^2 \leq (1 + c \Delta t) \|e^{n-1}_h\|_{L^2(\Gamma_h^n)}^2
\]

\[
+ \Delta t \rho_n^{-1} \|n_h^{n-1} \cdot \nabla e^{n-1}_h\|_{L^2(\Gamma_h^n)}^2 + c \Delta t \|u\|_{W^{m+1,\infty}(\mathcal{G})}^2 (\Delta t^2 + h^{2q} + h^{2m}),
\]

with a constant \( c \) independent of \( h, \Delta t, n \) and of the position of the surface in the background mesh. Applying the discrete Gronwall inequality proves the theorem.

\[\square\]
7. Numerical experiments. In this section, we present results of several numerical experiments, which illustrate the finite element method performance and analysis. All experiments are done using the finite element package DROPS [5]. To build computation mesh, we use the combination of uniform subdivision into cubes with side length $h$ and the Kuhn subdivision of each cube into 6 tetrahedra. This provides us with a shape regular bulk triangulation $\mathcal{T}_h$. The temporal grid is uniform in all experiments, $t_n = n \Delta t$ with $\Delta t = \frac{T}{N}$. We use piecewise linear bulk finite element space $V_h$ (e.g., (5.5) with $m = 1$) for both finite element level set function and for the definition of test and trial spaces in (5.14). This leads to geometry approximation (5.6) with $q = 1$.

**Example 1.** In the first example, we consider the Allen–Cahn equation on a sphere moving with constant velocity $w = (2, 0, 0)^T$. The corresponding level set function is given by

$$
(x - x_0(t))^2 + (y - y_0(t))^2 + (z - z_0(t))^2 = 1,
$$

(7.1)

with the center $x_0(t) = (x_0, y_0, z_0)^T = wt$. We consider the Allen–Cahn equation with nonzero right hand side term:

$$
\dot{u} + (\nabla \cdot w)u - \Delta u - \varepsilon^{-2}f(u) = g(x), \quad \text{on } \Gamma(t)
$$

(7.2)

such that solution is known explicitly:

$$
u = \frac{1}{2} \left( 1 - 0.8 e^{-40t} \right) \left( \sqrt{\frac{3}{\pi}} (y - y_0) + 1 \right).
$$

We set $\varepsilon = 0.1$, $T = 0.1$. The computational domain is $\Omega = [-2, 2]^3$; it contains $\Gamma(t)$ (and $\Gamma_h(t)$) at all times $t \in [0, T]$. The error is measured in the $L^2(\Omega; \Gamma(t))$ and $L^\infty(\Omega; \Gamma(t))$ norms of the error converges with the first order in space and time. The “experimental orders of convergence” (eoc) in space and time are then defined as $\text{eoc}_x = \log_2(e_b/e_a)$, where $e_a$ and $e_b$ are corresponding error norms. In particular, $\text{eoc}_x$ stands for the convergence order in space, when time is fixed. Likewise, $\text{eoc}_tt$ shows convergence order in time per two refining steps; and $\text{eoc}_xtt$ indicates the order for the simultaneous space and time refinement. From Table 7.1, we can see that in $L^2(\Omega; \Gamma(t))$ norm the error converges with the first order both in space and time (this agrees with our analysis), while the $L^\infty(\Omega; \Gamma(t))$ norm of the error reduces approximately four times if the mesh size is reduced two times and the time step is reduced four times. The observed rates are optimal for our choice of the finite element space and time-stepping scheme.

**Example 2.** We now consider the Allen-Cahn equation on a sphere of varying radius $R(t)$. The level set function of the sphere is given by

$$
\phi = x^2 + y^2 + z^2 - R(t)^2.
$$

It defines a pulsation of the sphere. We are interested if the numerical solution approximation a geodesic curvature type flow defined by (3.13). The phase separation curve $C(t)$ is initially a circle with radius $r_0 < R(0)$. Due to the axial symmetry, for all $t \in [0, t_{\text{crit}})$, $C(t)$ is a circle of radius $r(t)$, where $r(t)$ solves the ODE

$$
r_t = \frac{r^2 - R^2}{rr^2} + \frac{r}{R} r_t.
$$

(7.3)

Our reference solution is computed by the direct integration of (7.3) with a higher order Runge–Kutta method. We next solve the Allen-Cahn equation on the sphere and compare the radius of the zero level-set of the numerical solution with the reference solution. In this test, we set $R(t) = \frac{1}{\sqrt{1 + \delta \cos nt}}$, with $\delta = \frac{1}{2}$ and $n = 16 \pi$. We choose the final time $T = 0.125$ and $\delta t \approx 3.9063 \times 10^{-6}$. The radius evolution recovered from the finite element solution to the Allen–Cahn equation is shown in Figure 7.1. We can see that result is in a good agreement with the reference curve.
The initial manifold is given (as in [6]) by a uniform distribution.

The velocity field that deforms the surface is $\mathbf{w}(x, t) = \left(10x \cos(100t), 20y \sin(100t), 20z \cos(100t)\right)^T$. In this example, we choose a slightly different $f(u) = u^2(1 - u^2)$ so that solution is in the interval $[0, 1]$. The initial function $u_0$ is defined in each node by a random number from $[0, 1]$ using the uniform distribution.

In this example, we set $a = 1$, $\varepsilon = 0.01$, $T = 0.04$ and $\Omega = [-2, 2]^3$. We use the same bulk triangulation and spaces as in example 1 and $\Delta t = T/1024$. Figure 7.2 shows the (approximated) manifold and snapshots of the discrete solution $u_h$ at several time instances. In general, we note that the evolution of $u$ in this example is similar to what is found on the stationary surface $\Gamma(0)$ with surface FEM in [7]: the fast decomposition phase follows by the formation of phases with a narrow transition region (diffuse interface) between phases. As expected for the mean curvature motion, the interface tends to straightening, second phase regions are rounding and shrinking.

Table 7.1
$L^2(H^1)$- and $L^\infty(L^2)$-norm error in Experiment 1 with backward Euler.

| $L^2(H^1)$-norm of the error | $h = 1/2$ | $h = 1/4$ | $h = 1/8$ | $h = 1/16$ eoc$\varepsilon$
|-----------------------------|-----------|-----------|-----------|-------------
| $\Delta t = T/64$ | $5.3 \cdot 10^{-1}$ | $5.2 \cdot 10^{-1}$ | $5.1 \cdot 10^{-1}$ | $5.1 \cdot 10^{-1}$ | $1.60$

Example 3. In this example, we consider the surface Allen-Cahn equation (2.5) on a deforming manifold of a general shape. The initial manifold is given (as in [6]) by

$$\Gamma(0) = \{ x \in \mathbb{R}^3 \mid (x - z^2)^2 + y^2 + z^2 = 1 \}$$

The velocity field that deforms the surface is

$$\mathbf{w}(x, t) = \left(10x \cos(100t), 20y \sin(100t), 20z \cos(100t)\right)^T.$$
Fig. 7.2. Example 3: solutions for $t = k\Delta t$ with $k = 0, 32, 256, 512, 768, 1024$.
