# Nonlinear Optimization Problem

Nonlinear optimization problems:

$$\begin{array}{ll} \min & f(\mathbf{x}) \\ \text{subject to} & c_i(\mathbf{x}) = 0, \quad i = 1, \dots, m_e; \\ & c_i(\mathbf{x}) \geq 0, \quad i = m_e + 1, \dots, m. \end{array}$$

where,  $f(\mathbf{x})$ , and  $c_i(\mathbf{x})$  ( $i = 1, \dots, m$ ) are continuously differentiable functions from  $\mathbb{R}^n$  to  $\mathbb{R}$ . At least one of the functions  $f(\mathbf{x})$ , and  $c_i(\mathbf{x})$  ( $i = 1, \dots, m$ ) is nonlinear.

## Homework:

*NLP-Q1. What is the most important character of nonlinear optimization?*

# Outline

# Problem Classification - Unconstrained

$m = 0$  (Unconstrained Optimization)

- Quadratic minimization / Linear Least Squares:

$$f(x) = Q(x) = \|Ax - b\|_2^2$$

- Nonlinear Least Squares:  $f(x) = \|R(x)\|_2^2 = \sum_{i=1}^N r_i^2(x)$
- General Norm Minimization (Approximation)  
 $f(x) = \|R(x)\|_p$  (e.g.  $p = 1, \infty$ )
- convex unconstrained optimization:  $f(x)$  convex.

# Problem Classification - Equality Constrained

$m = m_e > 0$  (Equality Constrained Optimization)

- $f(x)$  quadratic,  $c_i(x)$  linear: Equality constrained QP.
- $f(x)$  nonlinear,  $c_i(x)$  linear: Linear equality constrained optimization.
- nonlinear equality constrained optimization.

# Problem Classification - General Constrained

$m > m_e \geq 0$  (General Nonlinear Constrained Optimization)

- Quadratic programming:  $f(x)$  quadratic and  $c_i(x)$  linear.
- Linearly constrained nonlinear programming:  $c_i(x)$  linear.
- general nonlinear constrained problems.

# Different Aspect of NLP

- Theory
- Method
- Algorithm
- Software
- Application

# Theory (Understanding the Problem)

- Optimal Conditions,
- Penalty Function,
- Dual Theory,
- Sensitivity,
- Solvability,
- Complexity,
- ...

# Method (How to Solve the Problem)

- Steepest Descent Method,
- Newton's Method,
- Conjugate Gradient Method,
- Sequential QP Method,
- Interior Point Method,
- ... ,

# Algorithm (Realization of Method)

Examples:

- inexact line search Newton's method
- an interior point algorithm for box constrained problems.
- a trust region algorithm for nonlinear LS.

# Software (Implementation of Algorithms)

- LANCELOT (Conn et al. 1992, Augmented Lagrangian)
- MINOS (Murtagh and Saunders 1982, Augmented Lagrangian)
- SNOP (Gill et al. 2002, SQP)
- NPSOL (Schittkowski 1983, SQP)
- KNITRO (Byrd et al. 2000, Interior Point)
- LOGO (Vanderbei and Shanno 1999, Interior Point)
- IPOPT (Vächter and Biegler 2004, Interior Point)
- NLPSPR (Betts and Frank 1994, Interior Point)
- FilterSQP (Fletcher and Leyffer 1998, Filter SQP)
- ...

# Applications (Not simply applying softwares!)

Special techniques can be applied because

- Special Structure
- Special linear/nonlinear properties

Applications in

- Science: (Information, Biology, Physics, ... )
- Finance:
- Transportation
- Defence

# Steepest Descent

$$\min_{x \in \mathbb{R}^n} f(x)$$

Steepest Descent Direction:

$$\mathbf{x}_{k+1} = \mathbf{x}_k + \alpha_k (-\nabla f(\mathbf{x}_k))$$

exact line search,  $\alpha_k^*$ :  $f(\mathbf{x}_k + \alpha_k^* \mathbf{d}_k) = \min_{\alpha > 0} f(\mathbf{x}_k + \alpha \mathbf{d}_k)$

Inexact line search,  $\alpha_k$  satisfies

$$f(\mathbf{x}_k + \alpha_k \mathbf{d}_k) \leq f(\mathbf{x}_k) + b_1 \alpha_k \mathbf{d}_k^T \nabla f(\mathbf{x}_k)$$

$$\mathbf{d}_k^T \nabla f(\mathbf{x}_k + \alpha_k \mathbf{d}_k) \geq b_2 \mathbf{d}_k^T \nabla f(\mathbf{x}_k)$$

$b_1 \in (0, 1)$ ,  $b_2 \in (b_1, 1)$ .

# Convergence of SD

Assume  $\|\nabla^2 f(\mathbf{x})\| \leq M$ .

$$f(\mathbf{x}_k) - f(\mathbf{x}_k + \alpha_k^* \mathbf{d}_k) \geq \frac{1}{2M} [d_k^T \nabla f(\mathbf{x}_k) / \|\mathbf{d}_k\|_2]^2$$

$$f(\mathbf{x}_k) - f(\mathbf{x}_k + \alpha_k \mathbf{d}_k) \geq \frac{b_1(1 - b_2)}{M} [d_k^T \nabla f(\mathbf{x}_k) / \|\mathbf{d}_k\|_2]^2$$

Either  $f(\mathbf{x}_k) \rightarrow -\infty$  or

$$\begin{aligned} \sum_{k=1}^{\infty} \|\nabla f(\mathbf{x}_k)\|_2^2 \cos^2 \langle \mathbf{d}_k, -\nabla f(\mathbf{x}_k) \rangle &= \sum_{k=1}^{\infty} [d_k^T \nabla f(\mathbf{x}_k) / \|\mathbf{d}_k\|_2]^2 \\ &\leq \infty \end{aligned}$$

For SD Method,  $\cos \langle \mathbf{d}_k, -\nabla f(\mathbf{x}_k) \rangle = 1$ .  $\|\nabla f(\mathbf{x}_k)\| \rightarrow 0$ .

# Convergence Rate of SD

Assume that  $f(x)$  is convex quadratic.  $f(x) = \frac{1}{2}x^T Hx$ ,  $H$  is a symmetric positive definite matrix. ( $g_k = \nabla f(x_k)$ )

$$\frac{f(x_k) - f(x_k + \alpha_k^*(-g_k))}{f(x_k)} = \frac{(x_k^T H^2 x_k)^2}{x_k^T H^3 x_k x_k^T H x_k} \geq \frac{\lambda_1(H)\lambda_n(H)}{(\lambda_1(H) + \lambda_n(H))^2}$$

where  $\lambda_1, \lambda_n$ : largest eigenvalue and the smallest eigenvalues.

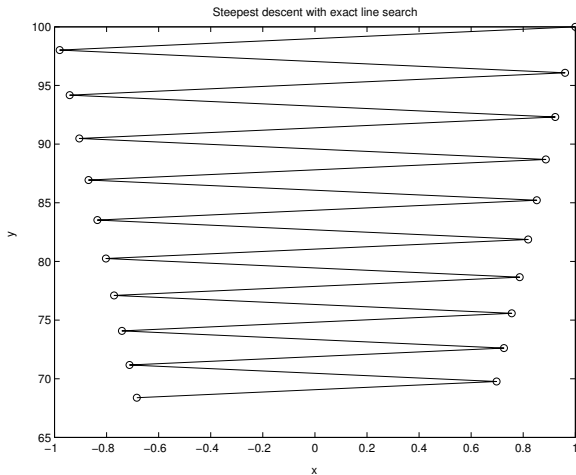

$$\frac{f(x_{k+1}) - f(x^*)}{f(x_k) - f(x^*)} \leq \left( \frac{\mu - 1}{\mu + 1} \right)^2 < 1.$$

$$\mu = \lambda_1(H)/\lambda_n(H)$$

Linear Convergence!

## Exact line search + steepest descent gives bad results

A typical behavior of the steepest descent method is illustrated in the following picture where 20 iterates are plotted for the objective function  $f(x, y) = 100x^2 + y^2$ , starting at the initial point (1, 100).

# BB method

The main idea of Barzilai and Borwein's

$$\mathbf{x}_{k+1} = \mathbf{x}_k - D_k \mathbf{g}_k, \quad \text{where } D_k = \alpha_k I.$$

Quasi-Newton property:

$$\min \| \mathbf{s}_{k-1} - D_k \mathbf{y}_{k-1} \|_2$$

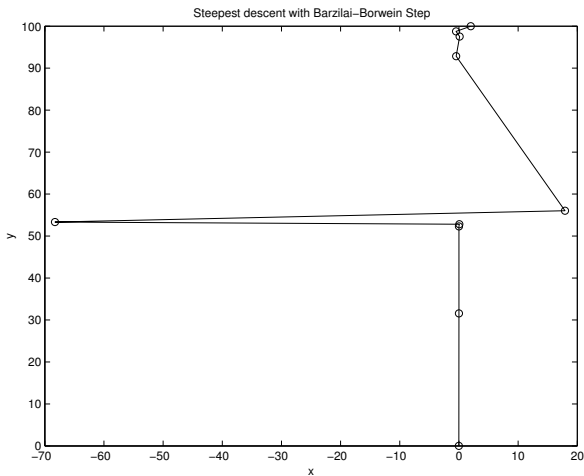

$$\min \| D_k^{-1} \mathbf{s}_{k-1} - \mathbf{y}_{k-1} \|_2$$

where  $\mathbf{s}_{k-1} = \mathbf{x}_k - \mathbf{x}_{k-1}$  and  $\mathbf{y}_{k-1} = \mathbf{g}_k - \mathbf{g}_{k-1}$ .

$$\alpha_k = \frac{\mathbf{s}_{k-1}^T \mathbf{y}_{k-1}}{\| \mathbf{y}_{k-1} \|_2^2}, \quad \alpha_k = \frac{\| \mathbf{s}_{k-1} \|_2^2}{\mathbf{s}_{k-1}^T \mathbf{y}_{k-1}} \quad (\alpha_{k-1}^* \quad !)$$

**THEOREM** *If  $f(x)$  is a strictly quadratic convex function with 2 variables. The BB method gives that  $\| \mathbf{g}_k \| \leq \eta \lambda^{-(\sqrt{2})^k}$ , where  $\lambda = \sigma_1(H)/\sigma_2(H)$ ,  $\eta$  is a constant independent of  $k$ .*

The behavior of the BB method for  $f(x, y) = 100x^2 + y^2$ , starting at the initial point  $(1, 100)$ .

# Cauchy Step too long

# Stepsizes for Gradient Method

- SS1 (Short Step I)

$$\alpha_k^{\text{SS1}} = \gamma_1 \alpha_k^*$$

- Short Step II

$$\alpha_k^{\text{SS2}} = \begin{cases} \gamma_2 \alpha_k^*, & \text{if } k \text{ is odd;} \\ \alpha_k^*, & \text{if } k \text{ is even,} \end{cases}$$

- AM (Alternating Minimization)

$$\alpha_k^{\text{AM}} = \begin{cases} \frac{g_k^T g_k}{g_k^T H g_k}, & \text{if } k \text{ is odd;} \\ \frac{g_k^T H g_k}{g_k^T H^2 g_k}, & \text{if } k \text{ is even.} \end{cases}$$

- RAND (Random Step)

$$\alpha_k^{\text{RAND}} = \theta_k \alpha_k^*,$$

where  $\theta_k$  is randomly chosen in  $[0, 2]$ .

# A New Step Size

**Question:** *finite termination for two dimensional quadratic problems?*

$$\alpha_k^Y = \frac{2}{\sqrt{(1/\alpha_{k-1}^* - 1/\alpha_k^*)^2 + 4\|g_k\|_2^2 / (\|s_{k-1}\|_2^2 + 1/\alpha_{k-1}^* + 1/\alpha_k^*)}}$$

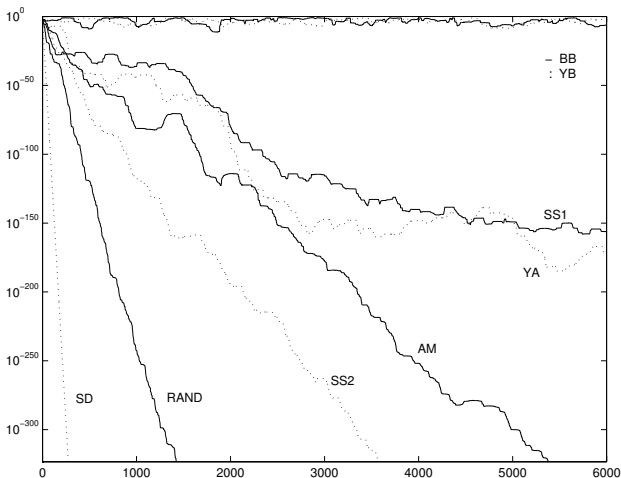

- Algorithm YA

$$\alpha_k^{YA} = \begin{cases} \alpha_k^*, & \text{if } k \text{ is odd;} \\ \alpha_k^Y, & \text{if } k \text{ is even} \end{cases}$$

- Algorithm YB

$$\alpha_k^{YB} = \begin{cases} \alpha_k^*, & \text{if } \text{mod}(k, 3) \neq 0; \\ \alpha_k^Y, & \text{if } \text{mod}(k, 3) = 0 \end{cases}$$

$$\xi_k = \frac{\min\{\sum_{j=0}^{L-1} |g_{k+j}^{(i)}|; i = 1, \dots, n\}}{\max\{\sum_{j=0}^{L-1} |g_{k+j}^{(i)}|; i = 1, \dots, n\}}$$

## Conjugate Gradient Method:

$$d_{k+1} = -g_{k+1} + \beta_k d_k$$

Idea: (Conjugate Property)  $d_k^T \nabla^2 f(x) d_j = 0$

Leading Choices for  $\beta_k$

- Fletcher-Reeves:  $\frac{\|g_{k+1}\|_2^2}{\|g_k\|_2^2}$
- Polak-Ribiere-Polyak:  $\frac{g_{k+1}^T (g_{k+1} - g_k)}{\|g_k\|_2^2}$
- Hensternes-Stiefel:  $\frac{g_{k+1}^T (g_{k+1} - g_k)}{d_k^T y_k}$
- Dai-Yuan:  $\frac{\|g_{k+1}\|_2^2}{d_k^T y_k}$

# Convergence of CG Methods

- For convex quadratic functions. Exact line searches imply
  - $d_k^T H d_j = 0 \quad (j = 1, \dots, k-1)$
  - $g_k^T d_j = 0 \quad (j = 1, \dots, k-1)$
  - $g_k^T g_j = 0 \quad (j = 1, \dots, k-1)$
- For general nonlinear functions, analysis techniques:
  - $\cos \langle d_k, -g_k \rangle = \frac{-g_k^T d_k}{\|g_k\| \|d_k\|}$
  - Lower bound for  $|g_k^T d_k|$
  - upper bound for  $\|d_k\|$

Example 1: For exact line search:  $|g_k^T d_k| = \|g_k\|^2$

Example 2: For F-R method:  $\frac{d_{k+1}}{\|g_{k+1}\|^2} = -\frac{g_{k+1}}{\|g_{k+1}\|^2} + \frac{d_k}{\|g_k\|^2}$

Modification of  $\beta_k$  for inexact line searches?

General coefficient for  $g_{k+1}$  instead of 1 ?

**Reason:** *Conjugacy is not necessary a good property when line search is not exact !*

**Aim:**

- Making  $d_{k+1}$  heading to the solution for two dimensional problem
- For general  $n$  dimensional problems, making the angle between  $d_{k+1}$  and  $x^* - x_{k+1}$  as small as possible

**Example** (Stoer and Yuan):  $d_{k+1} =$

$$\frac{(g_{k+1}^T y_k g_{k+1}^T s_k - s_k^T y_k \|g_{k+1}\|_2^2) g_{k+1} + (g_{k+1}^T y_k \|g_{k+1}\|_2^2 - \rho_k g_{k+1}^T s_k) s_k}{\rho_k s_k^T y_k - (g_{k+1}^T y_k)^2}$$

$$\rho_k \approx g_k^T \nabla^2 f(x_k) g_k$$

# Quasi-Newton

Newton's Method:  $d_k = -(\nabla^2 f(x_k))^{-1} g_k$

Quasi-Newton Method

$$d_k = -(B_k)^{-1} g_k$$

$B_k$  satisfies the **Quasi-Newton Equation**:

$$B_k s_{k-1} = y_{k-1}$$

Normally,  $B_k$  positive definite: "Variable Metric Method". (steepest descent direction if we use the norm  $\|d\|_{B_k} = \sqrt{d^T B_k d}$ )

# Major Quasi-Newton Formulae

**DFP** (Davidon-Fletcher-Powell)

$$B_{k+1}^{(\text{DFP})} = B_k - \frac{y_k s_k^T B_k + B_k s_k y_k^T}{y_k^T s_k} + \left(1 + \frac{s_k^T B_k s_k}{y_k^T s_k}\right) \frac{y_k y_k^T}{y_k^T s_k}$$

**BFGS** (Broyden-Fletcher-Goldfarb-Shanno)

$$B_{k+1}^{(\text{BFGS})} = B_k - \frac{B_k s_k s_k^T B_k}{s_k^T B_k s_k} + \frac{y_k y_k^T}{y_k^T s_k}$$

**SR1** (Symmetric Rank 1)

$$B_{k+1}^{(\text{SR1})} = B_k + \frac{(y_k - B_k s_k)(y_k - B_k s_k)^T}{(y_k - B_k s_k)^T s_k}$$

**Broyden Family:**  $B_{k+1}(\theta) = (1 - \theta)B_{k+1}^{(\text{BFGS})} + \theta B_{k+1}^{(\text{DFP})}$

# Properties of Quasi-Newton Method

- Invariance
- Conjugacy
- Quadratic Termination
- Least Changes

# Convergence Properties of Quasi-Newton Methods

**Theorem(Powell, 1971)** *The DFP method converges for uniformly convex functions if exact line searches are used.*

This theorem can be extended to all Broyden's family due to Dixon.

**Theorem(Powell, 1976)** *The BFGS method converges for general convex functions if inexact line searches are used.*

The above theorem has been generalized to Broden's convex family ( $\theta \in [0, 1]$ ) except DFP ( $\theta = 1$ ). (Byrd, Nocedal, Yuan)

Without convexity, even BFGS fails to converge (Dai)

## Question

*Whether DFP with inexact LS converges for convex funtions?*

# Convergence Rate for quasi-Newton Method

Superlinearly Convergence:

$$\lim_{k \rightarrow \infty} \frac{\|x_{k+1} - x^*\|}{\|x_k - x^*\|} = 0$$

For  $n > 1$ , least Q-Order is one, namely we can not prove

$$\|x_{k+1} - x^*\| = O(\|x_k - x^*\|^{1+\epsilon})$$

for any given  $\epsilon > 0$ .

Let 
$$\epsilon_k = \frac{\|x_{k+1} - x^*\|}{\|x_k - x^*\|}.$$

## Question

Could we prove  $\epsilon_k = O(\|x_{k-n} - x^*\|)$  ?

# Limited Memory Quasi-Newton

BFGS represented as:  $( H_k = B_k^{-1} )$

$$H_{k+1} = \left( I - \frac{s_k y_k^T}{s_k^T y_k} \right) H_k \left( I - \frac{y_k s_k^T}{s_k^T y_k} \right) + \frac{s_k s_k^T}{s_k^T y_k}$$

Limited BFGS formular:

- $H_k^{(0)} = \frac{s_k^T y_k}{y_k^T y_k} I$
- $H_k^{(j+1)} = H_{k+1}^{BFGS}(H_k^{(j)}, s_{k-m+j}, y_{k-m+j}), \quad (j = 0, 1, \dots, m)$
- $H_{k+1} = H_k^{(m+1)}$

$m = 0$  + exact line search  $\rightarrow$  conjugate gradient direction (DY)

**Advantage:** Only need to store  $(s_{k-j}, y_{k-i})(i = 0, 1, \dots, m)$ .

  - Trust Region
  - A Model Trust Region Algorithm
  - Trust Region Subproblem
  - Combinations of TR and LS

# Trust Region

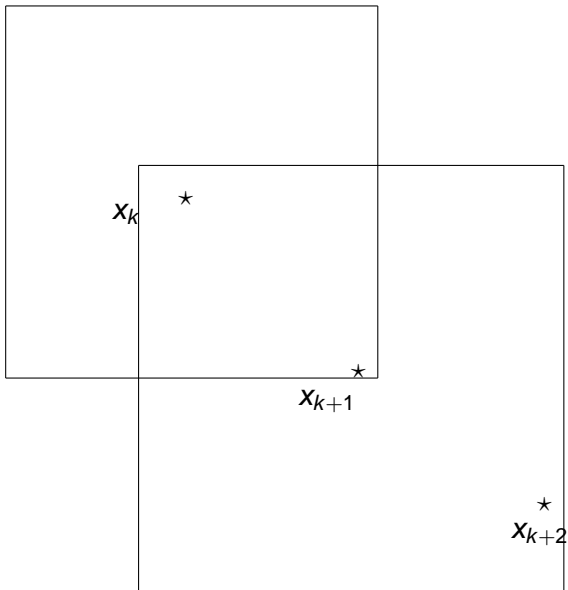

Main Idea: No line search,  
“search” in a REGION

- Current Iterate:  $x_k$
- Trust Region:  $R_k$
- Trial Step:  $s_k$

Motivation:

- Region better than a line
- When a search direction is not good, it is likely that the model is not accurate.

# Key Contents of a Trust Region Algorithm

- Computing the trial step
- Judging the trial step
- updating the trust region
- modifying the approximate model

# Levenberg-Marquardt Method

$$\min_{x \in \mathbb{R}^n} \|F(x)\|_2^2$$

where  $F(x) = (f_1(x), \dots, f_m(x))^T$ .

The Gauss-Newton Step:  $d_k = -(A(x_k)^T)^+ F(x_k)$

The Levenberg-Marquardt method

$$d_k = -(A(x_k)A(x_k)^T + \lambda_k I)^{-1} A(x_k) F(x_k)$$

which solves

$$\min_{d \in \mathbb{R}^n} \|F(x_k) + A(x_k)^T d\|_2^2 + \lambda_k \|d\|_2^2$$

$$\min_{d \in \mathbb{R}^n} \|F(x_k) + A(x_k)^T d\|_2^2$$

$$\text{s. t.} \quad \|d\|_2 \leq \|d_k\|_2$$

# A model TR for Unconstrained Optimization

– Trial Step  $s_k$ : Solving subproblem

$$\begin{aligned} \min_{d \in \mathbb{R}^n} \quad & g_k^T s + \frac{1}{2} s^T B_k s = \phi_k(s) \\ \text{s. t.} \quad & \|s\|_2 \leq \Delta_k \end{aligned}$$

where  $g_k = \nabla f(x_k)$

Predicted Reduction:

$$Pred_k = \phi_k(0) - \phi_k(s_k).$$

Actually Reduction:

$$Ared_k = f(x_k) - f(x_k + s_k).$$

# A Model Algorithm - Algorithm Descriptions

Step 1 Given  $\mathbf{x}_1 \in \mathbb{R}^n$ ,  $\Delta_1 > 0$ ,  $\epsilon \geq 0$ ,  $\mathbf{B}_1 \in \mathbb{R}^{n \times n}$  symmetric;  
 $0 < \tau_3 < \tau_4 < 1 < \tau_1$ ,  $0 \leq \tau_0 \leq \tau_2 < 1$ ,  $\tau_2 > 0$ ,  $k := 1$ .

Step 2 If  $\|\mathbf{g}_k\|_2 \leq \epsilon$  then stop; Compute  $\mathbf{s}_k$ .

Step 3 Compute  $r_k = Ared_k / Pred_k$  Let

$$\mathbf{x}_{k+1} = \begin{cases} \mathbf{x}_k & \text{if } r_k \leq \tau_0, \\ \mathbf{x}_k + \mathbf{s}_k & \text{otherwise;} \end{cases}$$

Choose  $\Delta_{k+1}$  that satisfies

$$\Delta_{k+1} \in \begin{cases} [\tau_3 \|\mathbf{s}_k\|_2, \tau_4 \Delta_k] & \text{if } r_k < \tau_2, \\ [\Delta_k, \tau_1 \Delta_k] & \text{otherwise;} \end{cases}$$

Step 4 Update  $\mathbf{B}_{k+1}$ ;  
 $k := k + 1$ ; go to Step 2.

  - Combinations of TR and LS

# Trust Region Subproblem

$$\begin{aligned} \min_{d \in \mathbb{R}^n} \quad & g^T s + \frac{1}{2} s^T B s = \phi(s) \\ \text{s. t.} \quad & \|s\|_2 \leq \Delta \end{aligned}$$

**THEOREM** (Moré and Sorensen, 1983)  $s^*$  is a solution of the Trust Region Subproblem TRS if and only if there exists  $\lambda^* \geq 0$  such that

$$(B + \lambda^* I) s^* = -g$$

and that  $B + \lambda^* I$  is positive semi-definite,  $\|s^*\|_2 \leq \Delta$  and

$$\lambda^* (\Delta - \|s^*\|_2) = 0.$$

# Exact solution of TRS

- $s^* = -B^{-1}g$
- $s^* = -(B + \lambda^*I)^{-1}g$
- $s^* = -(B + \lambda^*I)^+g + v$  (“Hard Case”)

Define  $d(\lambda) = -(B + \lambda I)^{-1}g$

Need:  $\|d(\lambda)\| = \Delta$  or

$$\frac{1}{\|d(\lambda)\|} - \frac{1}{\Delta} = 0$$

- $1/\|d(\lambda)\|$  is a “linear-like” function.
- Newton’s Method can be used.

# Inexact Solution of TRS

## Motivation:

- sufficient to ensure convergence
- save computations
- Newton's step near solution

## Main approaches

- dog-leg method (Powell, Dennis, Mei)  
Cauchy point and Newton Step
- 2-Dimensional Search  
 $Span\{-g, -B^{-1}g\}$
- Truncated CG method (Toint, Steihaug)  
precondition and truncation
- Semi-definite program approach (Rendl and Wolkowicz)

## 2 Dimensional Minimizer of TRS

**THEOREM** (Yuan, 1996) *Let  $s^*$  be the exact solution of trust region subproblem, and  $s_{2D}^*$  minimizes  $\min g^T s + \frac{1}{2} s^T B s$  subject to  $s \in \text{Span}\{-g, -B^{-1}g\}$ ,  $\|s\| \leq \Delta$ . There exists no positive constant  $c$*

$$\frac{\phi(0) - \phi(s_{2D}^*)}{\phi(0) - \phi(s^*)} \geq c.$$

for all  $B > 0$ .

**EXAMPLE**  $g = (-1, -\epsilon, -\epsilon^3)^T$ , and

$$B = \begin{pmatrix} \epsilon^{-3} & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \epsilon^3 \end{pmatrix},$$

where  $\epsilon > 0$  is a very small positive number.

$$\frac{\phi(0) - \phi(s_{2D}^*)}{\phi(0) - \phi(s^*)} = O(\epsilon)$$

# Truncated CG Step

**THEOREM** (Yuan, 2000) *Assume  $B > 0$ , let  $s^*$  be the exact solution of trust region subproblem, and  $s_{CG}^*$  is the truncated CG step by Steihaug's algorithm, then*

$$\frac{\phi(0) - \phi(s_{CG}^*)}{\phi(0) - \phi(s^*)} \geq \frac{1}{2}.$$

## Idea of Proof

- $\cos \langle -g, s_{CG}^* \rangle \geq \cos \langle -g, s^* \rangle$
- Define CG path
- $d_k \in S_k = \text{Span}\{g, Bg, B^2g, \dots, B^{k-1}g\}$
- $\text{Span}\{g, (B + \lambda I)g, (B + \lambda I)^2g, \dots, (B + \lambda I)^{k-1}g\} = S_k$
- exact solution expressed as CG solution

# Combining TR with Backtracking

TR+LS: (Nocedal +Yuan, 1991)

If  $s_k$  is not acceptable by TR,  $x_{k+1} = x_k + \delta^P s_k$  ( $\delta \in (0, 1)$ ,  $P > 1$ )

## Motivations:

- Trust Region Trial Step is descent
- Subproblem is difficult to solve
  - Under the Framework of TR method
  - Back-tracking if trial step is unacceptable
  - nice convergence results as TR
  - numerical results better than pure TR.

## Homework

*NLP-Q2. What is the main difference between LS and TR?*

*NLP-Q3. What is the similarity between LS and TR?*
